For the present, new patients are assigned appointments through their physicians for Tuesday, Thursday and Saturday afternoon. On arrival, a record is made by the clinic secretary of the economic status of the patient and of his family. If the patient is accepted, the referring physician is notified by letter that the diagnostic investigation has been begun and that he may expect to receive a detailed report on its completion. After admission, a secretary enters the preliminary data on the clinical record and the patient is taken to the laboratory. Pulse, respiration, temperature and weight are recorded by a nurse and then a number of preliminary routine laboratory procedures are performed, such as urine analysis, blood count, Kahn or Wassermann test for syphilis, and sedimentation test of the red blood cells. The blood obtained for the last test is then available for any chemical analyses that may subsequently be needed.

Each patient is then interviewed by the director or associate director of the consultation service, the referring physician's letter is read, and the patient is assigned to one of the internists. After the clinical history has been taken and the physical and fluoroscopic examination recorded, the details of the diagnostic investigation are planned by the internist in conference with the director or associate director. In addition to internists, a gynecologist and a laryngologist serve daily, and other consulting specialists are always on call. Many of the consultations and some special laboratory examinations can be completed on the first visit, such as blood chemical analyses, tests of renal or hepatic function, electrocardiography, oscillometry and certain roentgenologic procedures on parts of the body, such as the heart, lungs, sinuses and bones, which require no special preparation of the patient. On the intervening days of the week (Monday, Wednesday and Friday), patients return for special diagnostic procedures, such as basal metabolism determinations, Rehfuss or Ewald test meals, confirmatory reexaminations of various kinds, roentgenologic examinations, cystoscopies, proctoscopies, biopsies, and some of the specialist consultations.

Only rarely can the investigation be completed at the first visit. The patients average three or four visits, or about seven days for completion of the study. Unusually difficult or complicated cases require a longer period. Two or three additional days are necessary before all reports are received and recorded, the case summarized by the internist, and the final report to the referring physician is dictated by the director or associate director.

The final correlation and interpretation of all the observations devolves eventually on the director of the service. If there is any doubt about the accuracy of the diagnosis or the completeness of the investigation, the patient is summoned for a reexamination by the director or associate director before the final report is made to the referring physician.

### STAFF

The staff of the consultation service is recruited solely from the visiting staff of the hospital. For children, a pediatrician replaces the internist. Internists, gynecologists and laryngologists are on duty during the time of year when they are off ward service. All other consulting specialists are chosen from those who are on duty in the hospital because they are available every afternoon. This assures a gradual rotation of service among all members of the hospital staff. No distinction is made between associates and adjuncts. Full attending physicians are called whenever justified by the nature of the case, and they respond as promptly as the junior members of the visiting staff. The members of the visiting staff who participated in the diagnostic investigation of the first 350 patients included 11 internists, 2 pediatricians and 31 specialists (1 hematologist, 3 otologists, 4 laryngologists, 2 orthopedic surgeons, 2 genito-urinary surgeons, 3 general surgeons, 3 neurologists, 4 psychiatrists, 4 gynecologists, 1 dermatologist, 3 ophthalmologists and 1 dentist).

### COMPENSATION

Half the gross income per month is available for payment of the medical staff. The internists see two or three new patients in an afternoon, which requires from two to three hours. For this period of time, they receive credit for one work unit. Consultants are credited with half a unit for one consultation and with a full unit for two or more consultations during the same afternoon. The duties of the director and associate director demand three or four times as many hours a week as those of an internist, but, as the consultation service cannot afford to compensate them proportionately, they are assigned two units of credit for each actual clinic afternoon. In this manner their compensation does not depend on the time they spend in the consultation service, which must be unlimited.

At the end of each month, the value of the unit is determined by dividing the total number of units into half the gross income. Thus far the value of a unit has varied between $10 and $14. Specialist consultants, therefore, receive from $5 to $7 for each consultation. An internist who works three afternoons a week receives about $120 to $150 a month. This is somewhat more than is paid at other diagnostic clinics, but our internists and specialists are members of the visiting staff of the hospital.

The plan that has been adopted of sharing the gross income of the service between the participating physicians and the hospital is advantageous to both. Although the physicians are thereby relieved of financial responsibilities, the plan automatically keeps them interested in the administration of the service and in the economical utilization of its facilities.

### EXPENSES

One half of the gross income is available to defray the nonprofessional expenses of the service. If the total operating cost during the first year should exceed 50 per cent of the gross income, the deficit will be met by trustees of the hospital. If the operating cost should prove to be less than one half of the gross income, a share of the surplus will first be set aside for future replacements and any remainder will revert to the medical staff. As the service is designed for patients of very moderate means who cannot pay the full cost, the hospital has agreed to derive no profit from the operation of the consultation service either directly or indirectly.

The service has been in operation too short a period to determine how closely the payment of $35 will cover the average cost of a diagnostic investigation. Thus far a loss has been sustained, in spite of the fact that in estimating the operating cost no charge has been made for rent or for interest on the capital investment. The sums allotted each month to the roentgen and pathologic laboratories and other divisions of the hospital represent the full cost of the services which they have been called on to render during the current month. In arriving at estimates of the cost of services of this nature shared with other departments of the hospital, an equitable proportion of administrative and other general expenses has been included, but again nothing has been charged for rent or for interest on capital investment.

Any increase in gross income that may be expected as a result of the future growth of the service will tend to eliminate or at least materially reduce the operating deficit, for some of the fixed charges may be expected to remain unchanged even if the volume of work is eventually doubled. An increase in the gross income will have only a limited influence on the rate of compensation of the physicians per day or per patient, for under the elastic system employed a greater number of patients will always require a proportionately larger staff.

### VOLUME AND SOURCE

Although the consultation service ran at full capacity during December and January, there was a decrease in the number of patients referred during February. This was in part due to fading of the effect of circularizing physicians just before the service opened. In a larger part it was due to the fact that physicians made appointments for patients without informing them of the fee. Frequently, out of ten or twelve new patients who had been assigned appointments for an afternoon, three or four would cancel their appointment because they did not have $35. It has been quite obvious that only patients well within the prescribed economic level are being referred.

Table 1.—*Number of Patients Referred by Individual Physicians*

| | | |
|---|---|---|
| 216 physicians | referred | 1 patient each |
| 32 physicians | referred | 2 patients each |
| 11 physicians | referred | 3 patients each |
| 3 physicians | referred | 4 patients each |
| 1 physician | referred | 5 patients |
| 1 physician | referred | 7 patients |
| 1 physician | referred | 8 patients |

During the present month (March), the number of referred patients has again increased. This is probably due to a logical growth dependent on the many contacts established with physicians during the previous period. The first 350 patients were referred by 265 physicians, as shown in table 1.

This tabulation includes forty-two members of the staff of the Mount Sinai Hospital or outpatient department, who constituted 16 per cent of the total number of referring physicians and were responsible for referring sixty-four patients, or 18 per cent of the total number.

Table 2.—*Geographic Distribution*

| | Physicians | Patients |
|---|---|---|
| Manhattan | 103 | 72 |
| Bronx | 52 | 89 |
| Brooklyn and Queens | 54 | 95 |
| Richmond | 4 | 4 |
| Westchester County | 7 | 15 |
| Long Island | 6 | 18 |
| New York State (outside of Greater New York, Long Island and Westchester County) | 2 | 3 |
| Connecticut | 5 | 8 |
| New Jersey | 32 | 42 |
| Pennsylvania | .. | 2 |
| Massachusetts | .. | 1 |
| Canada (Toronto) | .. | 1 |
| Total | 265 | 350 |

### COMMENT

Many ambulatory patients of the type referred to the consultation service were previously hospitalized because their family physicians recognized that they could not afford to pay privately for a thorough diagnostic investigation, and some are still being referred for this purpose to the wards of the hospital. This is uneconomical for the hospital, the patient, and the hospital physicians. The cost to the hospital is thereby multiplied several times; the ward rate paid by the patient is about equal to the consultation service fee and he is deprived of an opportunity to continue his work; the physicians on ward duty receive no compensation for their professional services. The diagnostic investigation in the consultation service is often more intensive than in the wards because it is concentrated into a shorter time; the diagnostic facilities are more centralized; the consultations and conferences between internists and specialists are more intimate and, therefore, more satisfactory than in the wards. And not least important is the fact that a much closer relationship is maintainable between the physicians of the consultation service and the patient's family physician, both during the period of the investigation and at its conclusion.

If the activities of the consultation service should continue at the present level, about one thousand patients suffering for the most part from obscure and complicated illnesses will have received a searching diagnostic investigation during the first year. This represents a noteworthy expansion in the hospital's activities. It is equal to, or larger than, the total number of obscure diagnostic problems investigated in one of the medical divisions of the hospital of seventy beds during the course of a year. The medical problems presented by the patients of the consultation service are as important as those encountered in the hospital; in fact, they are apt to be more important to the patients because they represent the beginnings of disease, when patients are still in the operable or otherwise curable stage of their illness.

Viewed in its broadest aspect, the project represents an experiment in placing the professional and physical facilities of a large, well equipped general hospital at the disposal of the practicing physicians of the community for the benefit of patients of moderate means. Through the consultation service the hospital is making and maintaining new contacts with hundreds of physicians in the community, so that it is constantly expanding its scientific influence on the practice of medicine outside its walls.

---

# Book Notices

**Surgery of the Chest.** By George F. Straub, M.D., F.A.C.S. Cloth. Price, $10.50. Pp. 475, with 341 illustrations. Springfield, Illinois: Charles C. Thomas, 1932.

In this concise work the author covers the subject of chest surgery. The book is profusely illustrated with photographs and many pen and ink and wash drawings, as well as diagrams made by the author himself. The main articles on the literature of chest surgery have been condensed, and an excellent bibliography has been made. The chapter on x-rays in thoracic surgery is written by Dr. Arnold and illustrated with excellent copies of roentgenograms. Although the field of chest surgery is covered by Sauerbruch's monumental treatise in German, by Lilienthal's excellent two volume work in English, and by many fine monographs on special subjects, there is still a need for such a book as Straub's, which covers the whole field in a comparatively few pages. Most of the thoracic surgery in this country is done by men who have not the time to study either the innumerable original publications in the journals or the other works mentioned. The author has avoided taking a controversial stand on subjects in which the opinion of the authorities is still divided, by giving wherever possible the various theories and procedures. The book should appeal to the general surgeon who has neither the time nor the desire to go more deeply into the matter of thoracic surgery, and it might be read with profit by that large group of medical men who still consider that except for empyema there is little that can be done of a surgical nature to relieve thoracic and intrathoracic disease.

**Die ästhetische Chirurgie und ihre soziale Bedeutung.** Von Dr. A. Noel. Deutsche von der Verfasserin erweiterte und neubearbeitete Ausgabe. Übersetzt von Dr. A. Hardt. Mit einem Geleitwort von Prof. Dr. E. Meirowsky. Paper. Price, 7.50 marks. Pp. 72, with 112 illustrations. Leipzig: Ambrosius Barth, 1932.

This translation is of a presentation by Dr. Noel of her work devoted frankly to eradication of conditions impairing the esthetic values occasioned by skin laxity, puffiness of the lids and kindred phenomena. The selection is of a kind to minimize the element of reparative surgery and to constitute a frank advance to or over the borderline. Granted that there is a case to be made for those who have sound reasons in economic status or in mental suffering justifying such procedures, the deliberate standardizing of mere beauty procedures leaves something to be desired. Decisions should be individual rather than generic, exceptional rather than collective. Moreover, even ignoring the ethical objection, the methods here disclosed indicate a lack of thorough knowledge of the nature and relation of the facial tissues; and the indicated procedures themselves convey the same message.

**Kurzes Handbuch der Ophthalmologie.** Herausgegeben von F. Schieck und A. Brückner. Band VI: Auge und Nervensystem. Bearbeitet von C. Behr, F. Best und anderen. Paper. Price, 148 marks. Pp. 878, with 277 illustrations. Berlin: Julius Springer, 1931.

The sixth volume of this handbook of ophthalmology has appeared promptly as advertised and indicates that the whole series of seven volumes will be in the market well within the time announced by the publishers. This is in marked contrast to the larger Graefe-Saemisch, the second edition of which has been in the process of publication for more than thirty years and is not complete yet. Our own American Encyclopedia of Ophthalmology required several years more than first contemplated but finally appeared in its entirety before the war. The sixth volume of the Kurzes Handbuch is devoted to the eye and the nervous system and is divided as follows: the pathologic anatomy of the base of the brain, by F. Wohlwill of Hamburg; the pupil, by R. Bing and A. Franceschetti of Basel; diseases of the ocular nerves, by C. Behr of Hamburg; diseases of the optic tract from the chiasm upward, by C. Behr of Hamburg; diseases of the higher optical centers, by F. Quensel of Leipzig; ocular changes in organic noninflammatory diseases of the central nervous system, by F. Best of Dresden; ocular changes in inflammatory diseases of the central nervous system, by W. Kyrieleis of Würzburg; disturbances and changes in the visual apparatus in psychoses and neuroses, by the late L. W. Weber of Chemnitz; reedited by R. Runge of Chemnitz. As can be seen from the contents, this is essentially a reference book for the ophthalmologist, for it contains practically all the neurophthalmology ever needed. The one chapter the ophthalmologist should read in its entirety is the one on the pupil. Unfortunately this is not written as clearly as it should be, as the authors have analyzed and recorded the experiments and conclusions of various men with diametrically opposed opinions. It is perfectly true that our knowledge of the physiology and histopathology of the pupil and its reactions contains many gaps; but the differences of opinion should not be so emphasized as to cloud the known facts. Apart from this one phase, the chapter on the pupil is good. Interesting is the rather lengthy discussion of psychic blindness (*seelenblindheit*) by Quensel, a phase of ophthalmology that is not to be found in any of the ophthalmic literature. Taken on the whole, this volume offers an intensely interesting reference book but scarcely one that would be chosen voluntarily for light reading. The illustrations and the bookmaking are fully up to the high standards set by the preceding volumes, and so is accomplished one more step in what promises to be the most valuable reference handbook of modern ophthalmology.

**Textbook of Gynecology for Nurses.** By Philip J. Reel, M.D., F.A.C.S., Assistant Professor of Surgery, College of Medicine, Ohio State University. Cloth. Price, $2.50. Pp. 282, with 81 illustrations. Philadelphia: F. A. Davis Company, 1932.

The first chapters of this book are devoted to the anatomy, physiology and pathology of the external and internal genitalia. Then follow chapters which are of more special interest to nurses. These include sections on examination of patients, preparation of patients for operation, anesthesia, postoperative care and operating room equipment, personnel and technic. At the end of each chapter is a list of review questions. The illustrations are clear and instructive, particularly those depicting operating room and office equipment. The author is to be complimented for showing face masks that cover not only the mouth but also the nose and for calling attention to this. The book should prove helpful not only to pupil nurses receiving instruction in gynecology but more especially to supervisors of operating rooms and to graduate nurses who are preparing to be hospital or operating room supervisors.

**Miracles of Healing and How They are Done: A New Path to Health.** By J. Ellis Barker. Cloth. Price, 7/6. Pp. 404. London: John Murray, 1931.

Mr. Barker is a British journalist who has written some remarkably unscientific volumes in the medical field. Some of his previous writings have had the benefit of introductions by Arbuthnot Lane. Mr. Barker is the possessor of a vast credulity. As a result, he takes everything printed in the medical field as truth, citing numerous case reports from ancient textbooks in every field of medical cultism and making a great case for homeopathy. The book is worthless for any purpose except as a medical curiosity.

**Human Physiology: A Text-Book for High Schools and Colleges.** By Percy Goldthwait Stiles, Assistant Professor of Physiology in Harvard University. Sixth edition. Cloth. Price, $2.25. Pp. 448, with 82 illustrations. Philadelphia: W. B. Saunders Company, 1932.

This textbook for high schools and colleges was first published in 1916 and has since passed through numerous reprintings and revisions. Because of the systematic and simple character of the presentation, the book may be recommended for general reading. It is not, however, adapted to use by medical students.

## When Disease Is Not Attributable to Accident

*(Chase v. Business Men's Assurance Co. of America, (U. S. C. C. A.), 51 Fed. (2d) 34)*

The deceased was insured against disability caused by sickness and by bodily injuries. The policy, however, insured against death only when it resulted from "bodily injuries effected solely through accidental means," not when it resulted from disease. The insured died of typhoid fever. His widow, the beneficiary under the policy, sued the insurer for the benefits payable under it. She claimed that the death of the insured was caused by typhoid fever, "which was occasioned by and resulted from bodily injuries effected solely through accidental means, to wit, by his drinking polluted and contaminated water . . . believing such water to be pure and fit for drinking purposes." After a judgment on demurrer in favor of the insurer-defendant, the plaintiff appealed to the United States Circuit Court of Appeals, Tenth Circuit.

The question, said the court, is whether the death of the insured resulted "from bodily injuries effected solely through accidental means," and not from "disease." It is difficult, if not impossible, to draw an exact line of demarcation between bodily injuries and bodily disease. The two concepts are not always exclusive of each other; they often overlap. Usually pathogenic bacteria are taken into the system as incidents to normal bodily processes, and when disease follows, common understanding regards the introduction of the germs into the system, not as an accidental injury, but as the contracting of a disease, and common speech so describes it. On the other hand, when the channel of infection is abnormal—when infection enters through a bruise, a cut, or other trauma—the layman views the event as an accident, and in his everyday speech he refers to it as such.

When an accidental injury to the body causes a disease, and the disease in its turn causes death, the cases generally hold that the accidental means is the cause of the death. The disease is an effect of the accident and is merely the incidental means that brings about the fatal result; it is nothing more than a link in the chain of causation between the accident and the death, and the death is attributable to the accident. In the present case there was no bodily injury caused by accidental means, but only bodily injuries caused by disease, and these, under the terms of the policy, were excluded from its coverage.

Even if it should be assumed that typhoid fever is itself a bodily injury, the beneficiary under the present policy would be no better off. The policy by its express terms provides that it shall cover no injury caused by disease. It does not cover death from typhoid fever which is not brought about by an accidental bodily injury, unless the word "disease," as used in the policy, is construed as not including infectious and contagious disease. The language of the policy discloses no intent that would justify such a construction. On the contrary, the policy expressly provides that "blood poisoning or septicemia resulting from bodily injuries shall be deemed to be included in said term 'bodily injuries,'" and under familiar rules of statutory interpretation thus clearly excludes from the coverage of the policy "bodily injuries" caused by any other infectious disease. The fact that such an express provision with reference to septicemia was written into the policy shows that the parties believed that its other provisions excluded from its benefits injuries caused by infectious diseases.

In the judgment of the court, death resulting from typhoid fever was not within the coverage of the policy and the judgment of the court below in favor of the insurer was affirmed.

## Malpractice Suit Barred by Judgment for Fees

*(Garrett v. Kendrick et al. (N. C.), 160 S. E. 349)*

Garrett, injured in an automobile accident, was taken to a hospital owned and operated by Drs. Saliba and Bulla. Surgical treatment was given him by Saliba and by another physician, Kendrick. Later Saliba and Bulla, as owners and operators of the hospital, recovered a judgment against Garrett for bed, board and other hospital services and for the surgical services rendered by the hospital through Saliba. Garrett subsequently instituted a suit to recover damages for malpractice against Saliba, in which he joined Kendrick as a defendant. Judgment was rendered in favor of Saliba and Kendrick, and Garrett appealed to the Supreme Court of North Carolina.

When Saliba and Bulla sued Garrett for services rendered, they had to prove, said the Supreme Court, that such services were worth a certain amount. When the defendant Garrett defended the action against him on its merits, it was his duty to set up malpractice as a counterclaim, since the malpractice of which he complained grew out of the contract or transaction that formed the basis of the claim against him. In his present suit, Garrett alleged and the trial judge found that Saliba and Kendrick "acted jointly and in cooperation in said treatment and in the setting of the fractured bones of the arm and leg of the plaintiff." It seems, therefore, that on Garrett's own theory, Kendrick was a partner of Saliba in rendering the professional services out of which this litigation grew. When a court of competent jurisdiction renders judgment in a cause properly before it, such judgment estops the parties and their privies as to all issuable matters contained in the pleadings, including all material and relevant matters which the parties in the exercise of reasonable diligence could and should have brought forward. The judgment in favor of Bulla and Saliba in their suit against Garrett was necessarily an adjudication of the fact that both Saliba and Kendrick performed their services in an acceptable manner. Because of that judgment, Garrett could not now be heard to complain that he had been damaged by the negligence of either Saliba or Kendrick. The judgment of the trial court in favor of the defendants was therefore affirmed.

American Association for the Study of Goiter. [illegible] June 14-16. Dr. J. R. Yung, 670 Cherry St., Ter[illegible]

American Ophthalmological Society, New Lo[illegible] Dr. Emory Hill, 501 East Franklin Street, [illegible]

American Orthopedic Association, Toronto, Canada, June 15-18. Dr. DeForest P. Willard, 1916 Spruce Street, Philadelphia, Secretary.

Maine Medical Association, Rangeley, June 16-18. Dr. Philip W. Davis, 22 Arsenal Street, Portland, Secretary.

Medical Library Association, San Francisco, June 20-22. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.

Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.

New Jersey, Medical Society of, Atlantic City, June 15-17. Dr. J. B. Morrison, 66 Milford Avenue, Newark, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.

South Dakota State Medical Association, Watertown, June 20-22. Dr. John F. D. Cook, Langford, Secretary.

Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.

West Virginia State Medical Association, Parkersburg, June 21-23. Mr. J. W. Savage, Professional Building, Charleston, Executive Secretary.

Wyoming State Medical Society, Rock Springs, July 18-19. Dr. Earl Whedon, 50 N. Main Street, Sheridan, Secretary.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Question of Specific Myocardial Lesion in Hyperthyroidism (Basedow's Disease). W. Lewis, Hamburg, Germany.—p. 255.

**Intranuclear and Cytoplasmic Inclusions in Salivary Glands.**—In the submaxillary glands removed in a series of 183 postmortem examinations on infants, Farber and Wolbach found large cells containing intranuclear and cytoplasmic inclusion bodies ("protozoan-like bodies") in twenty-two cases (12 per cent). In addition, two older cases with inclusions in the parotid and submaxillary glands, and two instances in which inclusions were found in epithelial-lined spaces of the liver, lungs, kidneys, pancreas and thyroid are reported, making a total of twenty-six new cases to be added to the twenty-five already in the literature. All the patients in this series were less than 17 months of age, the majority being under 1 year. These inclusions are apparently identical with those found in the submaxillary glands of guinea-pigs and are generally similar to inclusions found in diseases due to filtrable viruses. Clinical and pathologic studies of the series reported reveal no association with any distinctive feature or group of symptoms or disease changes. The frequency of the inclusions in the authors' postmortem series suggests geographic factors affecting this occurrence and leads naturally to the suspicion of the existence of a disease, in infants, of filtrable virus etiology. However, if that is true, there are no distinctive clinical or pathologic features which would permit its recognition in the wards or in the pathology laboratory. The clinical and pathologic observations in the "positive" instances resemble, in general, the observations in the entire group studied.

**Changes in Dogs' Livers Following Constriction of Hepatic Veins.**—The livers of dogs examined by Simonds and Callaway twenty-four, forty-eight and seventy-two hours and seven days after mechanical obstruction of the hepatic veins for periods of from seven to thirty minutes showed the following changes: (1) A mean increase of 25 per cent in the liver weight-body weight ratio, due to edema and to swelling of the hepatic cells; (2) swelling, granulation vacuolization and extensive necrosis of the hepatic cells in the central half or two thirds of the liver lobules; (3) marked dilatation of the perivascular lymphatics surrounding the sublobular veins; (4) the presence of hyaline thrombi in many central and sublobular veins; (5) intrasinusoidal cell masses of two types: small, compact, occluding masses probably originating in "conglutination thrombi" of red cells, and larger, more diffuse and branching cell masses, and (6) hemosiderosis of Kupffer cells.

**Torula Infection.**—Watts presents two cases of torula infection. In the first the infection was generalized but the symptoms were almost entirely cerebral. A remarkable collection of pathologic changes were present in the brain: diffuse meningitis, granulomas in the meninges, marked endarteritis and proliferation of adventitial elements of the meningeal vessels, and infarct in the pons, areas of softening and focal disappearance of the granular and Purkinje cells in the cerebellum, diffuse ganglion cell changes, increase of neuroglia, nerve fiber destruction, myelin sheath damage, and encephalitis by extension in the striate body. The second case falls into the group which Freeman considers embolic phenomena. Mucicarmine was found to be an excellent differential stain, not only making it easy to identify the organism by its distinctive color but bringing out details of structure not heretofore recorded. Two strains of yeastlike bodies were isolated: the one producing no pigment falls into the torula group; the one producing pigment appears to be chromotorula. The organism was nonpathogenic for guinea-pigs, rats and mice. The author believes that the respiratory tract is probably the portal of entry in most cases. The infarct in the pons, endarteritis of numerous meningeal vessels with torula in the intima, and softenings in the cerebellum in one case add weight to the theory that cystic cavities in the deep white and gray matter are embolic phenomena and dissemination is by the blood stream.

**Effect of Cabbage Feeding on Thyroid of Rabbits.**—Zeckwer reports that feeding winter cabbage in the early part of 1931 to seventeen rabbits for periods up to 114 days produced hyperplasia of the thyroid, but only in two instances resulted in enlargements more than twice the normal weight. The microscopic changes of hyperplasia were more conspicuous than the gross enlargement. Under the conditions of these experiments, the feeding seemed to favor a high incidence of intercurrent infections. The data support the view that there is annual variation in the goiterogenic agent of cabbage.

**Gastric Acidity from Youth to Old Age.**—Vanzant and her associates call attention to the fact that satisfactory standards of normal gastric acidity have so far been lacking. They made a study of data from 3,746 persons in whom careful examination did not reveal any disease which could conceivably affect the mucous membrane or the secretory activity of the stomach. There was a steady increase in the incidence of achlorhydria from youth to old age. At the age of 60 years, 28 women in 100 (in the series) failed to show free acid on repeated fractional analysis, and, similarly, 23 men in 100 were achlorhydric. In an additional 5 per cent of women and 3 per cent of men there was no free acid in the first sample of an Ewald meal removed at the end of an hour. Free gastric acidity appears to increase rapidly from childhood up to the age of 20 years, when adult values are reached. About the age of puberty, the average value for boys begins to rise considerably above that for girls. In order to simplify the statistical study of the group of persons with free acid, all data from persons with true or apparent achlorhydria were first removed from consideration. One can now say that modal free acidity for men ranges between 45 and 50 units in the years from 20 to 40. After this it falls off rapidly to a level of from 30 to 35 units in the aged. The mode for women is approximately 35 units throughout adult life. It appears to fall off slightly after the age of 60 years. The normal range of free acidity in both men and women is about 90 units. The modal total acidity for women is practically constant at a level of about 51 units between the ages of 20 to 60 years; the mode for men ranges from 66 at the age of 20 years down to 56 after the age of 65 years. For both free and total acidity, mean and modal values were about the same. In both sexes the combined acidity appears to vary but little from youth to old age. Ninety per cent of the data lay between limits of 12 and 22 units, with a mode at 17 units. The data suggest that the process which gives rise to achlorhydria is not the same as the one that in men after 40 years produces a gradual falling off in acidity. The absence of such a gradual decrease in the older women makes it seem improbable that in either sex there is a progressive senile atrophy of the gastric mucosa.

**Effect of Ligation of Parotid Ducts on Carbohydrate Tolerance.**—Zimmerman reports that ligation of the parotid ducts in normal dogs results in an increased dextrose tolerance, as measured by the height of the blood sugar curve following the injection of dextrose solution. Histologic study of parotid glands removed at varying intervals after ligation of their ducts reveals only gradual dilatation of the ducts, with atrophy and fibrosis of the glandular parenchyma. Extirpation of the parotid glands in which the ducts had been ligated produced inconstant effects on the carbohydrate tolerance. Usually there was some increase in the height of the blood sugar curve, but the values rarely returned to the levels that had been maintained before the ducts were ligated.

**Effect of Prolonged Distention of Stomach in Dogs.**—Burgess and his associates found that continuous distention of the stomach with a volume of water introduced into a balloon —a volume twice that which would be ingested in the form of milk in hunger—caused grave morbid changes to occur in the wall of the stomach and resulted in death in twelve dogs within a period of from twenty-six to ninety hours without a significant fall in blood chlorides and dehydration. The cause of death was toxemia. The changes found at necropsy were not unlike those reported to occur in man in acute dilatation of the stomach. An electrocardiographic study revealed that distention of the stomach causes (1) a tachycardia with abolition of the normal sinus arrhythmia manifested by dogs, (2) inversion of the T wave or the accentuation of an inverted T wave present in some normal dogs, (3) accentuation of the Q wave, and (4) an exaggeration of preexisting electrocardiographic abnormalities.

**Tonsils in Young Women.** — According to Cunningham, the condition of the tonsils is of minor importance in influence on the health history and the determination of physical measurements of young women. Such influence is tangled with that of factors determining whether pathologic tonsils shall be removed or not and is therefore difficult to evaluate. The contention that normal tonsils are an aid in resisting disease is not strongly defended by contrasting the histories of disease of those with normal and those with pathologic tonsils. The argument that the removal of tonsils closes a portal of entry for infectious and respiratory diseases is not sustained by a comparative study of the histories of those who have had their tonsils removed and of those whose tonsils are present. The effect of the tonsils as a focus of infection does not find much support when histories and physical measurements of those with pathologic tonsils are contrasted with either those with normal or those with absent tonsils. The effect of normal tonsils in augmenting growth or of pathologic tonsils in retarding development is not apparent in this study. The effect of the tonsils on the glands of internal secretion is suggested in the thyroid observations but is not evident in comparative menstrual experiences or in the results of growth. The theory that the tonsillar condition is influenced by diet and reflects nutritional conditions, as may teeth, stature and weight, is not greatly aided by the observations of this investigation. The author's study does not emphasize the arguments for the removal of tonsils other than for the cure of a local throat condition.

**Psittacosis.** — Five cases of psittacosis occurring in one family are presented by Rabinowitz and Livingston, with necropsy observation in one. The disease in these cases was distinctly attributable to exposure to infected love birds or parrakeets brought to this country from Havana, Cuba, by returning tourists. This is of extreme epidemiologic and diagnostic importance. Biologic evidence of the identity of the disease was possible in this epidemic, the virus of psittacosis being clearly demonstrated in the sputum of one of the patients, in the liver, lung and spleen of another, and in the liver and spleen of the only bird available for examination. That this bird was apparently healthy is of great epidemiologic importance. The characteristic clinical points of diagnostic importance are: (1) history of exposure to a diseased bird; (2) incubation period of approximately nine days; (3) marked headache; (4) toxemia, which may be decidedly out of proportion to the physical observations in the chest; (5) slight cough with extremely scanty, thick, tenacious expectoration, which may or may not be blood tinged; (6) an extremely fine type of crepitant râle; (7) roentgen evidence of dense consolidation of part of a lobe of the lung almost from the onset of symptoms; (8) no pleuritic involvement in the face of extensive pulmonary pathologic involvement; (9) moderate or no leukocytosis in the presence of severe pneumonic infection, and (10) tendency to venous thrombosis.

**Serum Sensitiveness After Toxin-Antitoxin.** — Tuft states that after the administration of diphtheria toxin-antitoxin mixture containing minute amounts of horse serum, sensitization of varying degree occurs in 27.9 per cent of children. Such sensitization affects not only the skin but also other body tissues and is much more apt to occur in allergic children or children of allergic families. Reinjection of serums containing larger amounts of horse serum is in certain instances fraught with the danger of severe, immediate or accelerated serum reactions and may in most instances be prevented by the performance of a properly carried out skin test (in preference to the eye test) just prior to the administration and in the presence of a positive reaction, either by the use of a serum containing no horse serum or, if this cannot be procured, by spaced administration of increasing amounts of serum together with administration of small amounts of epinephrine. The continued use of diphtheria toxoid or of toxin-antitoxin prepared with goat serum antitoxin in active immunization against diphtheria will, in the future, prevent any possible development of sensitization to horse serum in immunized individuals and obviate the necessity for further precautions with serum reinjections.

**Effect of Caldwell-Luc Operation in Bronchial Asthma.**—Schenck and Kern report the results of the Caldwell-Luc operation as performed in thirty-five cases of bronchial asthma. The percentage of favorable results obtained bore no relation to the apparent etiology (allergy or infection), to the previous duration of the asthma or to the age of the patient. A comparison of these results with those of other intranasal operative procedures shows a greater percentage of improvement after the radical operation. In a majority of instances this improvement is only temporary. The authors believe that the radical operation should be reserved for those cases of antrum infection which have failed to yield to more conservative measures.

**Skin Reactivity to Meningococcus.**—Shwartzman reports that titrations of neutralizing antibodies of antimeningococcus horse serums with the aid of the auxiliary antibody disclosed wide fluctuations in their concentration during the immunization. A description is given of a simple and economical method of immunization which shows high titer of neutralizing antibodies for the phenomenon of local skin reactivity. Incidental observations reported are those on full antigenicity of meningococcus toxic filtrates, and also on the fact that the neutralizing antibodies may fluctuate in their concentration, while the agglutination and precipitation titers remain stationary.

**Typhoid Agglutinins Following Vaccine Injection.**—Lamson and Kessel gave thirty-six allergic patients numerous doses of typhoid vaccine in a period of several months to a year. Seven of them were given a total of 50 cc. or more during the course. These large doses did not produce a single untoward reaction. A few individuals gave a mild local or general reaction, but it usually followed one of the early treatments in the course. In one or two instances an injection seemed to precipitate a mild attack (or aggravate an existing one) of asthma. The observations are too few to make it certain that the injection had anything to do with the development of symptoms or to justify the conclusion that they were manifestations of a true allergy to the typhoid organism. A significant number of patients obtained relief during treatment and others seemed to gain weight more rapidly than is normal, even though their allergic state was not well controlled. It would appear that one is justified in assuming that those patients have had conferred on them a high degree of immunity to typhoid infection. The summary of the authors' observations indicates that the agglutinin titer is rather low, and there are but few reactions that would be considered suggestive if these serums were submitted for a routine Widal test.

**Antigenic Power of Toxin-Antitoxin Mixture.**—Githens describes experiments in which he demonstrated that toxin-antitoxin mixtures that are almost completely neutralized are as efficient antigens as those containing a great excess of toxin, and the immunity eventually obtained from toxic mixtures is no greater than that from almost completely neutral mixtures, although the maximum level may be obtained more rapidly. Two doses of 0.25 cc. each of toxin-antitoxin mixture are approximately as effective (in guinea-pigs) as one dose of 1 cc., although they contain only half as much toxin. Moderate differences in the L plus dose of the toxin used make little or no difference in the effectiveness of the mixtures as antigens.

**Effect of Grapes on Urinary Acidity.**—Saywell reports sixteen experiments with men subjects on basal diet and on the same basal diet supplemented by fresh grapes, fresh natural grape juice, detartrated grape juice, natural grape juice concentrate, concentrate-tartrate mixture, Thompson seedless and Muscat seeded raisins. The following results were observed when the grapes or grape products were added to the basal ration. 1. An increase in the $p_H$ of the urine occurred, ranging from 0.8 to 1.2 $p_H$ units. 2. A decrease in the ammonia excreted and a corresponding decrease in the total acidity was noted. 3. There was an increase of the alkali reserve above the normal for each subject, the alkali reserve being estimated by the plasma carbon dioxide combining power determined from the acid and ammonia content of the urine and calculated by the method of Fitz and Van Slyke. 4. A correlation between the alkalinity of the ash and the physiologic reaction was apparent. Grapes and grape products with the greater alkalinity of ash were associated with a more basic body reaction. 5. An increase occurred in organic acids excreted. This may be explained by the presence in the urine of some incompletely oxidized tartaric acid. 6. Approximately 94 per cent of the ingested organic acids appeared to be oxidized.

**Iron Requirement of the Preschool Child.**—Leichsenring and Flor conducted two iron-balance studies, using four healthy children, one boy and three girls, ranging in age from 35 to 56 months. Iron retentions at two levels of intake were compared. The results of the food analyses indicate that the iron content of foods may show considerable variation from the most commonly used figures. Diets that were planned to contain 5 and 8.5 mg. of iron actually contained only 3.25 and 6.5 mg. On a diet containing 3.25 and 6.5 mg. of iron, an average of 1.2 mg. was retained daily, whereas, on a diet containing 6.5 mg. of iron, 3.2 mg., or nearly three times as much as during the period of lower iron intake, was retained. The observed maintenance need of the children in this study was approximately 0.12 mg. per kilogram. It would appear from these results that, on the basis of body weight, the maintenance requirement of the child is similar to that of the adult. The iron requirement for growth, as observed in this study, was approximately 0.2 mg. per kilogram. In view of the differences observed between the actual iron content of the food used and the amounts as calculated from Sherman's tables, and also the pronounced individual differences in the iron requirement of children, it is suggested that a 50 per cent margin of safety be allowed above this observed total requirement of 0.32 mg. per kilogram. This would make a standard allowance for children of this age of 0.48 mg. per kilogram, or 0.62 mg. per hundred calories, or a total of 8.23 mg. a day.

*Effect of Ergotamine on Intestine with Observations on Influence of Calcium on Its Action. W. Salant and W. M. Parkins, New York.—p. 369.

**Effect of Radon Radiation on Isolated Organs.**—Gooding describes experiments in which he demonstrated that irradiation from radon causes an increased activity and irritability of certain isolated organs. This effect is greater if the perfusion fluid is partially deprived of potassium ions. Irradiation renders the uterus much more sensitive to the action of solution of pituitary.

**Ephedrine-Pituitary Extract Therapy in Histamine Shock.**—Melville presents experiments to show that a mixture of ephedrine sulphate and pituitary extract (posterior lobe) is more effective than larger individual quantities of these drugs in restoring blood pressure and respiration and in abolishing general collapse in dogs experimentally shocked by the prolonged intravenous injection of histamine. The prolonged and well maintained pressor effects of the mixture and the stimulant action of ephedrine alone on the central nervous system are suggested as the possible basis of these rather striking effects. Finally, the results suggest the possibility of applying to advantage this combined type of treatment in human cases of surgical shock and allied conditions of circulatory failure.

**Effect of Ultraviolet Rays on Toxicity of Nicotine.**—Wakeham and Tracy irradiated nicotine in quartz glass tubes for periods varying from fifteen minutes to five hours. Approximate minimal lethal doses of the different irradiated samples were determined by feeding gradually increasing amounts in 5, 10 and 20 per cent solutions to albino rats, until the lethal effect was obtained. Two groups of rats were used, one composed of animals 1 month old and the other of animals 3 months old. In each group the animals were approximately the same size and the same sex (male). No animal was fed nicotine more than once, whether it survived or not. It was noted that a maximum decrease of the toxic effect of nicotine on albino rats is obtained by an ultraviolet irradiation period of about one hour and fifteen minutes, the reduction in toxicity amounting to approximately 70 to 75 per cent. With further irradiation, the toxicity of the nicotine increases to nearly its original value.

**Picrotoxin as Antidote in Poisoning by Barbiturates.**—Maloney and Tatum present experimental data demonstrating the effectiveness of picrotoxin as an antidote in acute poisoning by the longer acting barbiturates. In sublethal doses of these compounds, picrotoxin shortens the recovery time, in lethal doses within certain limits it effects a cure, and in doses beyond the limits of hopeful therapeusis it prolongs the life of the animal. As types of the longer acting barbiturates, the following were employed: phenobarbital, neonal, ipral, barbital sodium, allylisopropyl barbituric acid, allylisopropyl barbituric acid mixed with amidopyrine in the ratio of three to five, and diallylbarbituric acid. Amytal, when administered orally in excess of the minimal lethal doses for that mode of administration, is successfully antidoted with picrotoxin. Through comparative studies on blood pressure, temperature and tissue changes, some light is shed on the mechanism of action of picrotoxin in the presence of the toxic effects of the barbiturates.

**Toxicities and Efficiencies of Local Anesthetics.**—MacDonald and Israëls describe a method by which measure of toxicity, relative toxicity and rate of destruction of local anesthetics can be obtained following slow intravenous infusion into cats. Figures for the relative toxicities of common local anesthetics are given, and some of the applications of these experiments to the clinical use of these drugs are discussed. A fair indication of the relative efficiencies of local anesthetics can be obtained in terms of relative efficacies (ratios of concentrations which achieve adequate anesthesia for any purpose) and relative toxicities.

**Effect of Ergotamine on Intestine.**—Salant and Parkins report that a single dose of ergotamine injected intravenously produces in cats and rabbits increased movements of the intestine. The effect may be obtained with doses of about 0.1 mg. per kilogram in cats and smaller doses in rabbits. The same amounts may sometimes produce a weak response or no effect when respiration is depressed, irregular or both. Repeated doses of ergotamine cause little or no effect or may even produce inhibition of the intestine. Atropine prevents the stimulating action of the intestine by ergotamine, indicating that the stimulation is due to the effect on the parasympathetic endings. The effect of multiple injections is probably due to depression of the muscle substance and fatigue of the nerve endings. Reversal of the depressing action of repeated doses of ergotamine may be produced by intravenous injections of calcium chloride. Intravenous injections of sodium oxalate which produce a decrease of blood calcium increases the depressing action caused by ergotamine and may also decrease the stimulating effect of the initial dose. The effect of excess and of deficient calcium on the action of ergotamine is discussed and an explanation is suggested.

**Case Fatality of Communicable Disease.**—Wood states that case fatality ratios are the proportion of deaths which actually occur in a known number of cases of any disease, that is, the number of cases per death. Case fatality ratios indicate the completeness of reporting of a disease and show the virulence of the disease. Correct case fatality ratios depend on complete reporting and the determined actual number of deaths among the persons whose cases have been reported. Correct ratios cannot be computed from the usual vital statistics tabulations. The following case fatality ratios are approximately correct: diphtheria, from 15 to 19 cases to 1 death; measles, 500 to 1; scarlet fever, 100 to 1; typhoid, from 8 to 12 cases to 1 death; whooping cough, from 125 to 150 cases to 1 death. Any state whose ratio of reported cases to recorded deaths falls much below those figures is obtaining incomplete reporting and therefore incomplete control over its quarantinable diseases.

**Tubercle Bacilli in Blood Stream of Rabbits.**—Mishulow and Park describe two experiments which seem to indicate that there is rapid localization of the tubercle bacilli inoculated into the blood stream, as shown by the tremendous decrease in their number between *twelve and twenty-four hours* after inoculation, and the steady decrease up to the fourth day. The organisms persisted in the blood stream throughout the entire course of the infection, although they fluctuated in number from day to day. There was a marked rise in numbers on the day of death. This would justify the conclusion that there is a steady dissemination of the tubercle bacilli from the local lesion into the blood stream.

**Relation of Bovine Mastitis to Human Infection.**—According to Brooks, mastitis is common among dairy cattle and the infection is readily communicated from one cow to another. The types of streptococci that are the common incitants apparently are not infective for man but when present in milk in large numbers with their toxins may be responsible for severe toxic disturbances, especially in children. Organisms, of animal or human origin, pathogenic for man may be present in diseased udders. These include the tubercle bacillus, Brucella abortus and the hemolytic streptococci which are incitants of septic sore throat and scarlet fever. Udders infected with Brucella abortus may excrete the organisms during the life of the animal. Agglutination and complement fixation tests on milk from infected quarters have given positive results, that from uninfected quarters negative. Agglutinating power in the blood may be due to infection localized in the udder. Several milk-borne epidemics of septic sore throat in upper New York State have been traced to raw milk from herds with cases of mastitis. In the more recent epidemics, hemolytic streptococci corresponding to those found in the human cases have been obtained from the infected udders. Recent experience suggests the desirability of persistent effort to find the infected cows. One epidemic of scarlet fever in 1922 was traced to raw milk, including that from a cow with mastitis from which hemolytic streptococci were obtained. Experience suggests that organisms from human sources are primarily responsible. Since Jan. 1, 1924, six outbreaks of gastro-enteritis have been traced to raw milk from herds in which there were cases of mastitis. In three of these, most of the patients were children given the milk in school. Illness developed within four or five hours. Cows with chronic mastitis were involved, and common types of nonhemolytic streptococci isolated. The author believes that bovine mastitis is a major problem in the prevention of milk-borne infection. A slowly developing movement for eradication offers no practical and immediate solution, nor will careful dairying methods and inspection afford adequate protection. Pasteurization is the only practical safeguard.

New Organic Compound for Use in Chronic Ear Suppuration. S. Stein, New York.—p. 219.

**Development of Nose.**—Carter calls attention to the fact that the development of the nose is largely a mechanical proposition. The septum is the most important factor in the elevation and subsequently in the support of the nasal bridge; consequently every operator should be ever mindful of the fact that neither cartilage nor bone, removed from the septum, is ever replaced, and that conservatism should always be practiced in doing the submucous operation. In the treatment of traumatic injuries, when it is possible, replacement of the fractured and dislocated parts should be practiced. This is imperative in the young subject; otherwise a deformity is certain to develop, though it may not become noticeable for several years. In developmental deformities, an effort should be made to adjust the parts so that the lines of force shall be so directed that they will construct a normal organ. If there is a deficiency in material for reconstruction, autogenous bone and cartilage transplants from the rib should be used in the manner first advocated by the author. Under no circumstances should foreign materials, such as paraffin, celluloid or ivory, be used for this purpose, as they are not safe nor do they remain permanently in the living tissues.

Treatment of Early Cases of Knock Knee and Bowleg in Children. E. Cyriax.—p. 35.
Unusual Case of Multiple Lipomas in Boy, Aged 2 Years. W. R. Bett.—p. 39.

**The Allergic Child.**—Bray states that the treatment of the varied allergic manifestations of childhood resolves itself into a definite routine, and the reliance on one therapeutic agent for all cases, or the shotgun principle of an assemblage of many in the hope that one will hit the mark, is to be deprecated. At times it is the acute exacerbation that one is called on to relieve, while at other times one is consulted as to the means of preventing further recurrences. The acute symptoms can generally be relieved by the hypodermic injection of a few minims of 1 : 1,000 solution of epinephrine hydrochloride or ephedrine given by mouth, ⅛ grain (8 mg.) to a child under one, ¼ grain (16 mg.) to a child over one year. It is well to realize that children do not stand the continued administration of ephedrine at all well, frequent complaints including an inability to micturate, insomnia, tiredness and fretfulness during the day, and occasionally cardiac dilatation and murmurs. In the prevention of further relapses, the first step is to endeavor to determine a specific cause or causes, from the history or by skin tests or elimination diets, and to insure their avoidance or removal. In addition, in the majority of cases several contributory factors operate and need attention. Good hygienic surroundings are essential as well as peace and harmony. The diet should be chosen to avoid specific causes of reaction. The child should be encouraged to eat a good breakfast and have a hot midday meal and a light, early supper. No food or drink should be given to the patient after he gets into bed. A proper balance between fats, proteins and carbohydrates should be determined, with a sufficiency of vitamins and salts. At the same time any foci of sepsis or irritation should be removed. If the cause cannot be removed, desensitization may be attempted. Specific desensitization may be accomplished by the ingestion of gradually increasing doses of the allergen, if a food, or by denaturization by boiling or cooking, or by subcutaneous injection if an inhalant. Nonspecific desensitization may be attempted if the cause cannot be determined, but results cannot be relied on.

Peptone, tuberculin, milk, autohemotherapy and vaccines have been advised. In many cases, prominent symptoms must be treated with drugs. In the pulmonary group, sedatives for the bronchial mucous membrane in the form of linctures may be required, in hay fever ointments or douches for the nose or drops for the eyes, and in the cutaneous manifestations palliative lotions or ointments. In the majority of allergic conditions there is a hypochlorhydria and hypoglycemia, so that the administration of hydrochloric acid and dextrose by mouth is indicated. In some of the skin manifestations and asthma, physical therapy at times brings about improvement, but it must be used only by skilled technicians or violent reactions will follow.

**Chronic Streptococcal Toxemia.**—Hindley-Smith calls attention to the fact that clinical research suggests the existence of an acute disease having invariable characteristics, for which the name "acute streptococcal fever" has been proposed. Other workers who have been studying the condition of chronic rheumatism have suggested that this is also due to the streptococcus acting under conditions of cell sensitization in the affected organism. A careful analysis of a large number of cases has led the author to the conviction that chronic rheumatism may be due to other causes than the streptococcus but that the streptococcus does, in fact, produce a disease having a definite syndrome and which is recognizable in its various stages, and of which the later symptoms include chronic rheumatism. Support for the theory that there is a condition of allergic sensitization at work in these cases, in addition to the streptococcal infection, is to be found in the fact that treatment with specific autogenous vaccines produces a high percentage of success.

**Pathology and Treatment of Anemia.**—Witts discusses the anemias that result from disturbances of nutrition and disorders of the alimentary tract. They form a group that impresses both by its size and its unity. It is his opinion that all are of nutritional origin. The normal human diet contains substances which are necessary for the maturation of megaloblast into normoblast, such as vitamin B and the active principle of liver, and others which are necessary for the maturation of normoblast into erythrocyte, such as vitamin C, thyroxine, iron, and traces of other minerals. Animal experiments suggest that food substances are also necessary for the development of the megaloblasts from the reticulo-endothelium of the marrow, and that their absence leads to aplasia. Anemia arises whether these substances are not supplied with the diet or whether they are not absorbed in digestion. The anemia is due to diminished blood formation or anhematopoiesis, and, according to the level at which hematopoiesis is arrested, the marrow may be normoblastic, megaloblastic or aplastic. The cells drafted into the circulation from this dysplastic marrow are sometimes abnormal and liable to early destruction, but hemolysis is always secondary to the degeneration of the bone marrow and is never of high degree. The reticulocyte count is low, the resistance to hypotonic solution of sodium chloride is little impaired, and hemoglobinemia and hemoglobinuria never occur. The white cells and the platelets are normal or diminished. Remission of the disease is attended by an outpouring of reticulocytes in numbers directly proportional to the extent of the hyperplasia of the bone marrow. All these features are in direct contrast to the hemolytic anemias. Clinically these anemias are characterized by their frequent association with glossitis, gastro-intestinal disorders and degeneration of the nervous system. Some of these anemias are simple and uncomplicated: the nutritional anemia of infancy is entirely due to shortage of minerals in the milk, and the anemia of scurvy to shortage of vitamin C. In others, the effects of one deficiency predominate in the blood picture, but traces of other defects may be recognized, as when iron deficiency occurs in Addison's anemia, or of the liver principle in simple achlorhydric anemia. In other cases, again, the symptoms of multiple deficiency may be present together, as in the anemia of pellagra or in tropical macrocytic anemia. The blood picture may change during the evolution of the primary disease. Megalocytic anemia is constant in Addison's anemia, but it is not uncommon for the disease to begin as a microcytic anemia, and more rarely it terminates in aplasia. This sequence of events is almost the rule in sprue.

**Treatment of Diabetic Uremia with Dextrose Solutions.**—Fullerton and his associates report the case of a woman, aged 27, who was admitted to the hospital unconscious, with marked air hunger, exhaling acetone strongly, and with the urine loaded with sugar and acetone. The case was diagnosed as diabetic coma. The patient was covered with warm blankets and surrounded with hot water bottles. At noon, 50 units of insulin was injected subcutaneously. Within half an hour she partially regained consciousness, and 30 Gm. of dextrose was given orally. At midnight a catheter was passed, and only 1 ounce (28 cc.) of urine was found in the bladder. Sugar and acetone were present, but much less in amount, while only a trace of diacetic acid was found. Blood was withdrawn, and the result of the estimation done next morning showed that the blood sugar was 382 mg. per hundred cubic centimeters. The blood urea had risen to 55 mg. per hundred cubic centimeters and the chlorides remained approximately stationary, at 627 mg. per hundred cubic centimeters. The patient was given 30 Gm. of dextrose and 20 units of insulin. During the first twelve hours she received 190 units of insulin and 150 Gm. of sugar. At 5 a. m. the bladder again contained only an ounce of urine, in which a trace of sugar and acetone was found, and no diacetic acid was present. Air hunger was absent, so further insulin treatment was temporarily discontinued. At this time vomiting was first noticed. For the following four days the patient was practically anuric, since approximately 2 ounces of urine was all that could be obtained each twenty-four hours by repeated catheterization. A consideration of these facts led the authors to conclude that the condition of the patient had altered from diabetic coma to what might be described as diabetic uremia. The position appeared to be critical, since patients with diabetic coma who develop a definite anuria, and in whom the blood urea reaches 150 mg. per hundred cubic centimeters or over, invariably die. Simple remedies, such as hot fomentations and cupping the loins, had failed. Irritant diuretics appeared to be contraindicated, as judged by the presence of blood and casts in the urine. As a last resort it was decided to try to restart urinary secretion by raising the blood sugar level to a high degree by the intravenous administration of hypertonic solution of dextrose. Accordingly, at 5 p. m. and again at 10 p. m., one pint of a 25 per cent solution of dextrose in physiologic solution of sodium chloride was given intravenously. The solution was introduced slowly, about forty minutes being taken for the injection. At 12:30 a. m., 8 ounces of urine was passed; this contained some sugar but no diacetic acid. During the rest of that day 20 ounces was passed. At 7:30 the next day another pint of 25 per cent dextrose in physiologic solution of sodium chloride was given intravenously. On the following two days, 34 ounces and 52 ounces of urine were passed, and subsequently normal urinary secretion occurred. The blood urea, which on the sixth day after admission had reached a maximum of 230 mg. per hundred cubic centimeters, steadily fell and returned to normal figures in nine days. The plasma chlorides, which up to this date had been somewhat above normal, fell to a figure slightly below normal. The patient's nutrition became excellent, and a complete recovery was achieved.

**Specificity of "Proteose" Intradermal Reactions.**—According to Freeman, Oriel's "proteoses," no matter where obtained or on whom tested, show a fairly constant toxic reaction within a few minutes of injection into the skin. (They may also show a delayed reaction.) He can detect no trace of the specific skin reactions claimed by Oriel. An immunotherapy based on this alleged specificity has no scientific foundation.

**Duration of Red Lochia.**—Moir found that the duration of a colored vaginal discharge following childbirth in 250 hospital patients varied considerably, but in the great majority of cases it far exceeded the supposed normal time limit. The average duration was twenty-four days. The average duration of the colored lochia in cases of uterine subinvolution and of retroversion was not greater than the average of the total number of cases. In this series there were twenty-nine cases in which suckling was not carried out. Those cases did not show any prolongation of the colored lochia. Age and parity had no appreciable effect on the duration of the colored lochia.

*Driver's Thigh. J. Hoets.—p. 265.

**Relation of Achlorhydria to Carcinoma of Stomach.**—Apperly and Norris call attention to the fact that there is much evidence that the achlorhydria that so commonly accompanies carcinoma of the stomach really precedes that condition. Achlorhydria may be acquired, the result of chronic gastritis, or it may be a congenital familial peculiarity. Investigations by the authors indicate that the achlorhydria is not of the latter variety and support Hurst's contention that it is the result of a chronic gastritis preceding the appearance of carcinoma.

**Nasal Sinusitis in Relation to Lobar Pneumonia.**—Eadie reports the results of 103 postmortem examinations of the nasal accessory sinuses. The cases were not selected in any way; the sinus examinations were carried out on patients who had died in the wards of the Melbourne Hospital and who came to necropsy. In few cases had a record been made of any examination of the nasal sinuses, carried out during the final illness. The diagnosis of the condition of the sinuses was formed from their macroscopic appearance. It would appear after reviewing these cases that there is a definite association between acute infection of the maxillary antrum and lobar pneumonia, and that the inflammatory reaction of the lung may be caused in many cases by the entrance into the lung by way of the larynx of pathologic organisms and their toxins that have developed in the maxillary antrum. The investigation seems to justify the following conclusions: 1. In all cases of lobar pneumonia, the maxillary antrums should be investigated, and this is most satisfactorily done by suction and disinfection of their contents. The earlier this is done, the better will be the prognosis when the antrums are infected. It is remarkable the improvement in general symptoms and signs that may occur after once these cavities are treated in this way. Also it is noted how often a single "wash out" seems sufficient to clear the suppurative condition of the sinus. At the first suction pure pus may be obtained, and on repetition of this procedure ten days later the contents may appear free of pus. 2. In regard to pneumonia in association with influenza, this procedure is particularly advocated. 3. When cerebral symptoms arise in the course of lobar pneumonia, the sphenoidal sinuses should be similarly dealt with. The suction and disinfection of the sinuses can be done with the minimal disturbance to the patient. He does not require to be moved in his bed. A local anesthetic is all that is required.

**Driver's Thigh.**—Hoets draws attention to a condition fairly well recognized by both medical and nonmedical motor drivers and suggests the name "driver's thigh," which seems both convenient and descriptive. If a label has already been affixed, it has escaped the author's notice. The condition is a neuralgia or a neuritis of the sciatic nerve observed in those who spend a fairly large part of their time driving a motor car. Symptoms vary from an ill defined feeling of fatigue of the thigh muscles to those of a classic sciatica. The cause is a long continued pressure on the sciatic nerve just before its division in the lower third of the thigh. The pressure is produced by the use of the accelerator pedal, which requires the foot to be held in the one position, often for long periods. Treatment is, of course, by having the seat adjusted. It would seem that the seat without the usual tilt is perhaps the best kind for the driver. The trouble comes only when the driver sits badly or the springs of the seat have given way.

**Abnormal Form of Polycystic Kidney.** — Papin and Verliac state that a patient operated on by one of them had a condition which they called polycystic kidney, but there was no resemblance to true polycystic kidney or to nephritis with cysts. The patient was an emaciated woman, aged 31, with a mobile kidney and with sand in the urine, but no calculi, although she had had nephritic colic and hematuria. In the course of the operation, which had to be conservative, the authors removed a kidney which contained an adenoma and which on histologic examination was found to contain multiple cysts. These cysts were situated in the medulla and all the pyramids. Only two or three occupied the columns of Bertin. The cysts were filled with a homogeneous material whose reactions were similar to those of amyloid material. Their wall was formed by a single layer of endothelium.

*Posttonsillitic Pyemia: Enucleation of Tonsils During Course of Peritonsillar Abscess and Acute Tonsillar Inflammations. N. Taptas.—p. 414.

**Chancroid Antibodies in Serum of Patients with Inguinal Adenopathies.** — Ravaut and his associates report the study of the formation of chancroid antibodies in the serum of patients with inguinal adenopathy. Studies of the deviation of complement in the presence of an antigen extracted from the bacillus of Ducrey were made on the serums of three groups of patients: (1) those with chancroid buboes, (2) those with poradenitis and (3) a control group. Ninety-one reactions were observed. The serum of patients with chancroid buboes in almost all cases gave a positive complement fixation reaction in the presence of a chancroid antigen; on the other hand, the reaction was almost regularly negative in patients with poradenitis. The antibody content of the serum following injections of streptobacillary vaccine (dmelcos) likewise revealed a fundamental difference between the two diseases. Vaccine therapy during the course of chancroid infection caused a considerable increase in the proportion of antibody in the serum (20 or 25 units of complement or more in place of the normal amount of 5 units). This increase followed intramuscular as well as intravenous injection and was of long duration. In poradenitis, vaccine therapy produced only a transitory appearance of antibody, which frequently remained a moderate proportion and was induced only by intravenous injection. This reaction, artificially produced, always became rapidly negative again. The behavior of the control subjects, also with suppurating adenopathies, was similar in all points to that of the group with poradenitis. The study of the reaction of the deviation of complement in patients with chancroid buboes and patients with poradenitis has some practical value because it may aid in the differential diagnosis of those relatively frequent inguinal adenopathies which do not present a characteristic clinical picture. However, the intradermal reaction with chancroid as well as with lymphogranulomatous antigen gives earlier, more sensitive and more constant reactions than the serum antibody reactions. Further, the intradermal reaction with the antigen of Frey constitutes a positive diagnosis in poradenitis, whereas the reaction of complement fixation with chancroid antigen only permits diagnosis by elimination. While admitting that the practical value of the complement fixation reaction does not equal that of the investigation of cutaneous allergy, the authors think the information furnished by this reaction has considerable theoretical value because it supplies an additional argument in favor of the difference in the nature of chancroid infection and poradenitis.

**Posttonsillitic Pyemia.**—Taptas discusses posttonsillitic pyemia, as to pathogenesis, diagnosis and therapy. He thinks that in posttonsillitic pyemia the infection spreads along the lymph channels to the lymph nodes in the region of the jugular vein and from there by continuity to the latter. Frequently the venous walls become infected before disintegration of the lymph node and formation of a cervical phlegmon. In other cases, formation of a peritonsillar abscess and a deep phlegmon of the neck appears first and it is not until much later, if one delays unduly the drainage of these pus collections, that the cervical veins may be attacked. Histologic examination of the tonsils which are the starting point of the pyemia reveals perivascular infiltrations, and the peritonsillar venules, even in cases in which the tonsils appear clinically healed, are often thrombosed. At the onset of pyemia all tonsillar inflammation may have disappeared, also pus in the tonsillar, peritonsillar or retrotonsillar region may be absent, but inflammation of the lymph nodes around the jugular vein always exists, if one knows how to find it. While it is impossible to tell in the beginning of a case of acute tonsillitis whether it will terminate in pyemia, the hope of recovery depends on early intervention; so the author advises being constantly on the watch for it and suggests several methods of procedure for the physician, depending on the condition of the patient at the time he first sees him. If the tonsillitis persists after a week or if remission of symptoms is followed by recurrence and formation of a peritonsillar abscess impends, it is better to perform enucleation of the tonsil immediately to prevent formation of the abscess, hasten the cure of the infection and prevent its spread to distant parts of the body. If on the first visit to the patient the tonsillitis is cured but the temperature remains elevated with remissions of septic fever, or there is continuous fever without chills and the cervical region at the angle of the maxilla is more or less sensitive or infiltrated, an incision should be made at the anterior edge of the sternocleidomastoid to inspect the jugular vein. If the vein is diseased or a deep phlegmon is found and drained, the tonsil which served as the portal of entry should be removed before the end of the operation. If the vein is healthy, exposure for examination by a small aseptic incision is not harmful. Waiting till symptoms of pyemia appear endangers the life of the patient. In cases in which the patient is first seen several days after the onset of tonsillitis and a peritonsillar abscess has already formed, if the jugular region is free and the abscess well formed, an incision of the soft palate can be made and the abscess drained; but if this appears difficult it is better to enucleate the tonsil. In this way, by removing the inner wall of the abscess, the cavity is transformed into an open wound permitting the best possible drainage. If the first examination reveals tonsillar or peritonsillar inflammation accompanied by an engorgement of the jugular region with high fever, tonsillectomy must be supplemented by exposure and inspection of the sheath of the large vessels. In such cases one sometimes finds a deep collection of pus with extensive detachment of the pharyngeal wall, drainage of which is followed by cure. At other times the veins of the neck are involved without the formation of an abscess and it is necessary to dissect and resect them. Here one should remember that in deep collections of pus as much as in thrombosis of the jugular vein, the skin and subcutaneous tissue remain entirely healthy, the lesions being located below the deep cervical fascia. It is difficult, even in case of an advanced lesion, to feel a definite hardness at this depth; trying to feel a hard cord to diagnose thrombophlebitis exposes the patient to irreparable lesions.

*Local Vaccine Therapy in Enterocolitis. A. Besredka.—p. 452.
Subcutaneous Rupture of Tendon of Long Extensor of Thumb. J.-L. Lapeyre.—p. 456.

**Local Vaccine Therapy in Enterocolitis.**—Besredka discusses local vaccine therapy in enterocolitis and reports some of the experiences of other investigators with this type of therapy which substantiate his observations and theories. By local vaccine therapy the author means specific immunization of an organ or tissue, effected without the aid of known antibodies and usually resulting in immunity of the entire organism. After discussing the development of this therapy and its use in streptococcus and staphylococcus infections, the author discusses its application in intestinal diseases such as typhoid, paratyphoid, cholera, dysentery and enterocolitis, in which the intestine is the sole or chief habitat of the infecting organism. Animal experiments demonstrated that ingestion of killed cultures of dysentery bacillus, cholera vibrio or typhoid and paratyphoid bacilli preceded, in the case of cholera or typhoid, by ingestion of ox bile to promote access of the organism to the intestinal wall resulted in a substantial immunity to infection. The method has been frequently and successfully used for vaccination in man. Seeking to discover whether this therapy could be used in enterocolitis, the author and his co-workers demonstrated in animal experiments that this method of local vaccination was also effective in the treatment of infection with Bacillus coli. Rabbits, after ingestion of living cultures of B. coli were able to resist lethal doses of the virus given intravenously. Corroborating experiences of other investigators are cited. In discussing the application of this therapy in various forms of enterocolitis, the author divides these into two groups: the monomicrobic, due to infection with typhoid-paratyphoid bacilli, dysentery bacilli, cholera vibrio, B. coli, Bacillus proteus and so on, and the polymicrobic or real enterocolitis which, the specific etiologic agent being unknown, must be considered as due to the collective action of all the intestinal bacteria. Two cases of B. coli infection are reported in which oral administration of an autogenous vaccine immediately after ingestion of bile resulted in cure. In cases in which the B. coli infection is complicated by urinary disturbances, the latter sometimes recede following oral vaccine therapy, but sometimes instillation of the antivirus into the bladder is required. In cases in which the colon bacilli persist in the urine after remission of the functional disturbances, if one can ascertain that the infection is localized in the upper part of the renal apparatus, one should not hesitate to introduce the antivirus into the kidneys. In fifty cases of colon bacilluria so treated by Jabiel and Petetin, symptoms of colitis and of bladder irritation disappeared in the first days of treatment. In some cases the bacteria persisted in the urine, but all signs of inflammation disappeared. Examples of successful oral vaccination against other monomicrobic forms of colitis are cited. Local vaccination in polymicrobic forms of enterocolitis, such as mucous colitis, sigmoiditis and ulcerative colitis, although more difficult, is practiced in France by many clinicians. Surmont and Butiaux employed the oral administration of autogenous vaccine, after sensitization of the intestinal mucosa with bile, in more than a hundred severe cases of enterocolitis with excellent results. The cure of a case of purulent hemorrhagic rectocolitis by local vaccination and its beneficial results in the treatment of ulcerative colitis have been reported by different authors. Amelioration or cure of the intestinal disturbances following local vaccination is accompanied in a good many cases by improvement or disappearance of the symptoms of perivisceritis, hypertension, anemia and cutaneous disturbances which sometimes accompany enterocolitis.

**Late Abscess Following Intragluteal Injection of Bismuth and Sulphur.**—Schaer relates the clinical history of a man, aged 34, in whom a large subcutaneous abscess developed following antisyphilitic treatment by means of intragluteal injections of bismuth and of sulphur preparations. Puncture of the abscess yielded a brown fluid in which bismuth could be detected but no sulphur. Bacteriologic examination of a smear, as well as the culture and the animal experiment, all gave negative results. Since puncture proved ineffective for the cure, two longitudinal incisions were made, and the abscess was drained. This treatment effected an immediate reduction in temperature, and after five weeks only a small fistula, the size of a pin head, remained. Because the general condition had also considerably improved, the patient was discharged from the hospital. The author points out that in the literature there are reports of other cases of late abscess after bismuth injections, and he cites several of them. He then calls attention to the fact that the patient who was the subject of his report received intermittently injections of sulphur. It is not impossible that injections of the sulphur preparations into the bismuth depot produced a toxic bismuth-sulphur compound that in turn could have produced a necrosis. However, the fact that in the pus there was only bismuth but not sulphur demonstrable speaks for the diagnosis of bismuth abscess.

*Pathogenesis and New Treatment of Varicose Ulcer. L. Biancalana.—p. 382.

**Pathogenesis and New Treatment of Varicose Ulcer.**—In a brief sketch of the anatomophysiology of circulation in the lower limbs, Biancalana states that the venous flow is occasioned by both (1) extrinsic propulsion, the push of arterial blood, thoracic aspiration, venous compression by muscular contraction and pulsations of the nearby arteries, and (2) intrinsic propulsion, venous elasticity and contractility. The author explains the genesis of varicosities in terms of venous insufficiency. The stasis and decrease in blood pressure of the venous network causes transudation of the plasma; the plasma distends the tissues, hindering interstitial circulation. The venous stagnation and the edema in turn hinder arterial circulation. In phlebitis, the venous walls are transformed into rigid tubes in which the circulation is poor. Ulcers are produced where the tissues are altered, and chronic ulcers are caused by nonspecific bacteria. Varicose ulcers do not respond quickly to treatment: it is seldom that the ulcerating tissues find the resources necessary for a restorative process. The treatment of the varicose ulcer is identical with that of the varices because in both the causal factor, stasis of the blood, must be eliminated. When the treatment of varices fails because of ulcer, measures are applied that can favorably influence circulation and cutaneous trophism of the limb. Modern therapy has turned to the method of obliteration of the veins. The substances promoting the process of endophlebitis, causing venous obliteration and sclerosis, are sodium carbonate and salicylate, quinine hydrochloride, mercuric iodide, sodium chloride, glycerin and phenol solutions. This method is bloodless and requires neither hospital care nor suspension of habitual occupation. It is useful in cases in which the cure of the varices did not heal the ulcers and in recurrent ulcers. The ambulatory treatment combats circulatory stasis of the limb by compressed bandages. After successfully treating ten patients, the author advocates the following technic. 1. The ulcer is cleaned preferably with benzine. 2. Then follows a superficial cauterization of the granulations with silver nitrate. 3. A thin layer of protective ointment (preferably Unna's) is spread on the ulcer and ulcerated zone. 4. The ulcer is covered with gauze padding to act as an absorbent of the secretion. 5. A bath sponge (about 2 cm. thick) covers the whole ulcer and is held in place by a gauze bandage. 6. A semielastic bandage is wound tightly about the leg from foot to knee, to keep the sponge compressed. The function of the sponge is to exert a regularly distributed pressure over the whole area. 7. The patient must walk about. (This treatment cannot be given to those confined to bed or with an acute attack of phlebitis.) 8. Dressings are changed every two or three days.

*A Peculiar Type of Hypoplastic Corpuscular Myelosis. P. Molteni.—p. 190.
Methods of Identifying the New-Born. F. Rolando.—p. 206.

**Peculiar Type of Hypoplastic Corpuscular Myelosis.**—Molteni describes a grave type of blood disease in a child, aged 6 years, and appearing some time after what is supposed to have been an attack of malaria. There were pallor of the skin and mucous membranes, hepatomegaly, great splenomegaly, practically no subjective symptoms, and nonprogressive but intermittent course of the disease, with periods of improvement and of exacerbation. The blood picture was characterized by diminution of red blood corpuscles, hemoglobin, leukocytes and platelets, with intermittent presence of basophil, polychromatophil and orthochromatic erythroblasts, few myelocytes and metamyelocytes, and absence of megaloblasts and megalocytes. The hematopoietic system presented zones of hyperplasia of the myeloid elements and aplasia of the elements producing the morphologic components of the blood, and in the spleen were found notable erythropoietic foci. This disease may be regarded as a variant of aplastic global myelosis, from which it differed in the variations of the clinical course, the blood picture and the histopathologic manifestations of the marrow, which throws light on certain types with a long course that may be observed in the adult. Malaria had no doubt an important part as a preparatory dysergic factor, in connection with a defective constitution, in the pathogenesis of the grave hemopathy. The course, although prolonged, proved fatal within one year and the many therapeutic attempts gave scarcely any results.

Peculiar Roentgen Aspect of Pneumothorax Complicated by Adhesive Pleuritis. M. Accorimboni.—p. 130.
Roentgen Therapy of Vaquez's Disease. R. Rossoni.—p. 156.

**Peculiar Roentgen Picture in Pneumothorax.**—Torelli describes twelve cases of pneumothorax in which the relation between the opacity of the collapsed lung and the transparency of the pneumothoracic cavity was reversed, the opacity of the cavity being more marked than the shadow of the lung. This roentgen picture, which the author terms "opaque thorax," might be explained by assuming a thickening of the parietal pleura of the pneumothoracic cavity.

Calcium and Potassium in Mumps. C. A. Videla and E. Savino.—p. 785.

**Sign Produced by Forced Extension of Neck.**—Videla explains that he has obtained flexion of the lower extremities in 50 per cent of the meningitic patients he has examined. He raises the upper part of the body and supports it with his left hand on the back of the patient while his right hand exerts pressure on the chin of the patient to obtain forced extension of the neck. He describes the case histories of twenty patients with meningitis, of which eight were tuberculous, seven meningococcic, two pneumococcic, two purulent and one syphilitic. Frankly positive signs were obtained in nine cases and a faint sign in one other case, the distribution being the following: five positive in eight tuberculous, two positive in two pneumococcic, two positive in two purulent and one faint in seven meningococcic patients.

**Antitetanic Serum Therapy Intravenously.**—Videla and his co-workers offer a preliminary report on the intravenous use of a concentrated antitetanic serum prepared by one of them in the Bacteriologic Institute of the National Department of Hygiene, review its application in six tetanus patients, of whom five died notwithstanding very active treatment, and offer the following conclusions: Specific treatment of tetanus with concentrated serum administered intravenously does not offer difficulties, and the use of *high dosage does not* produce shock, but the intravenous route is not more efficacious than the intramuscular route.

Action of Hormones in Acute Infections. H. J. Lauber.—p. 613.

**Chondrosarcoma of Bones.**—According to Kienböck, a chondrosarcoma of the bones may develop even during early childhood. Then it grows slowly during many years and even decades and finally reaches a considerable size. It may also form metastases in the internal organs as well as in the skeleton itself. In spite of this steady growth, the pains and other complaints are comparatively slight; only in the late stages does cachexia develop and then death follows. A detailed case history illustrates these aspects. In this case backache and scoliosis, the first symptoms, appeared at the age of 14. Roentgen examination at the age of 18 revealed a tumor the size of a hen's egg on the fourth lumbar vertebra. The tumor increased gradually up to head size, and a secondary cranial tumor developed, which also reached great size. The liver became enlarged and the skin showed Addison's pigmentation. The patient became apathic, emaciated and pale and died in his thirty-second year. The necropsy revealed a chondrosarcoma of the lumbar vertebrae and multiple foci in the internal organs and in the bones. In the conclusion the author states that although the final prognosis in such cases is unfavorable, it should also be considered that the patient may live with the primary tumor as well as the metastases many years and even decades.

**Hemorrhages of Renal Pelvis.**—In a case of severe hemorrhage of the renal pelvis in which nephrectomy was done, Ebhardt detected in the histologic examination that the hemorrhage was of inflammatory origin, was submucous, and was accompanied by proliferation of the epithelium. The kidney itself showed no essential changes. From this the author concludes that the term essential renal hemorrhage, as it is used in the modern literature, should be employed with greatest reserve, since in nearly all carefully examined cases a cause could be found for the hemorrhage. The reason for the absence of hemorrhages in one case and the presence of severe hemorrhages in another case giving an apparently identical histologic picture has as yet not been determined. The possibility of toxic influences from the respective infections on the vascular walls is considered.

**Surgical Aspects of Abdominal Purpura (Henoch).**—Three cases with certain similarities, which came under Seifert's observation in a comparatively short time, induced him to study the literature on the connection between abdominal purpura and intestinal invagination. He then describes the three cases of his own observation. The first one, which concerned a youth, aged 19, makes it appear probable that subserous hemorrhages in the end of the ileum in adults constitute a variation of purpura abdominalis (Henoch) in children. In the second case (true purpura abdominalis in a child, aged 10) surgical treatment was resorted to because appendicitis or invagination was thought of, but there were only hemorrhages in the intestinal wall, by which the wall had acquired a peculiar rigidity; but it is probable that this condition had caused the acute spasmodic abdominal pains. In a third case, which concerned a boy, aged 8, purpura abdominalis was combined with invagination and the author thinks that this is not a rare condition. The surgical significance of Henoch's purpura he sees in the fact that the spasmodic abdominal pains with vomiting and occasional bloody stools may mask an invagination, and since without a surgical intervention the diagnosis invagination can be based only on the palpation of the characteristic tumor, he thinks it advisable to resort to laparotomy whenever an invagination is thought probable, for it is better to perform an unnecessary laparotomy, that is, if there is only an abdominal purpura, than to overlook an actually existing invagination. The laparotomy is the more justified because there is also the possibility of an acute appendicitis. The abdominal purpura does not make an operation unusually dangerous, for it does not involve anomalies in the bleeding process, since the morphologic blood picture, the coagulation and the bleeding time are all normal.

**Hiccup as Symptom of Tension of Ligamentum Teres Hepatis.**—Büttner questions whether hiccup is always caused by contractions of the esophagus (cardia). A triad of symptoms attracted his attention, namely: (1) pains from the umbilicus upward, (2) a burning pressure that reaches underneath the sternum and simultaneous rising of watery mucus, which leads to frequent expectoration, and (3) hiccup. He cites observations which indicate that traction in the epigastric region such as is caused by tension of the ligamentum teres hepatis causes hiccup. The hiccup thus produced is always of a mild nature. It appears that the substernal pains, the heartburn-like manifestations and the expectoration are likewise caused by this tension. The most important practical result of his observations the author sees in the possibility that a group of complaints which have frequently been considered and treated as neurosis of the stomach can thus be explained and can be corrected by an operative intervention.

**Hormone of Intermediary Lobe of Hypophysis.**—Zondek and Krohn report their studies on the chromatophoric substance of the hypophysis. As a test object for this pigment hormone the authors used the minnow (Phoxinus laevis), a small fish, which at the spawning time develops the so-called nuptial dress, an intensive coloration on certain parts of the body. Attempts to produce the nuptial dress outside of the spawning period by means of the usual sex hormones (folliculin and prolan) failed, but it was found that, when a hypophyseal extract was injected that did not contain prolan, the minnows developed an intensive red coloration at the sites of attachment of the pectoral, ventral and anal fins. Microscopic examination revealed that this red coloration was due to a maximal expansion of the erythrophores. Since the erythrophores belong to the same cell group as the melanophores, it seems probable that the red coloration is produced by the melanophoric or chromatophoric substance of the hypophysis. The authors give a detailed description of their tests and state that they succeeded in isolating the chromatophoric substance as a special hormone, and that this hormone is produced in the pars intermedia of the hypophysis.

**Symptoms in Chronic Agranulocytosis.**—Doxiades relates the clinical histories of three patients with severe leukopenia or agranulocytosis in which the disease took a chronic and perhaps a benign course. In one of these cases there existed a reduction of the granulocytes for three years, with occasional latent intervals. During this period the patient passed through numerous infections, during which low as well as higher leukocyte values could be demonstrated. The transition from almost complete disappearance of the granulocytes to normal values of polymorphonuclear leukocytes took place without any therapeutic intervention whatever.

**Etiologic Studies on Lymphogranulomatosis Inguinale.**—Levaditi points out that until 1930 it was assumed that either a culturable micro-organism or a protozoan might be the cause of lymphogranulomatosis inguinale. Then, however, Hellerström and Wassen reported their experiments on monkeys, which indicated that a virus is the pathogenic agent. The author repeated the experiments reported by these investigators and obtained the same results. He further compared the virulence of several strains of the virus and he found that it varied greatly. He also investigated the biologic qualities of the virus, that is, its resistance to heat and cold and to various chemical substances. He found that it is a filtrable virus and that under the influence of electrophoresis it shows the same action as other types of virus, such as the virus of herpes, of encephalitis and of chicken cholera. Studies on the suitability of the various species of experimental animals for tests on the virus of granulomatosis inguinale revealed that only monkeys (not rabbits, rats and cats) are susceptible to the virus. The symptomatology of granulomatosis inguinale in monkeys varies according to the mode of inoculation, whether intracranial, intrapreputial or intra-inguinal. In intracranial inoculation, those symptoms predominate which indicate irritation of the cerebrospinal meninges. However, intrapreputial or intra-inguinal inoculations produce a bilateral inguinal polyadenitis, similar to that observable in human beings, but there are no indications of an involvement of the nervous system. Studies on the distribution of the virus in the organism of inoculated monkeys revealed that the virus is present in all organs. In regard to immunity and to the virucidal power of the serum in lymphogranulomatosis inguinale the author states that there are indications that during the disease the serum of the patient contains the virucidal principle, and he thinks that this factor may eventually be utilized for serodiagnosis and for serotherapy of the disease.

Surgery of Colon. H. Finsterer.—p. 665.

**Incarceration of Anastomotic Loop in Mesocolic Opening in Gastro-Enterostomy.**—Torraca points out that von Hacker was the one who first advised fastening the margins of the mesocolic opening to the posterior wall of the stomach in order to prevent contraction of this opening and incarceration. Most surgeons followed this suggestion, but others suggested fastening on the suture of the anastomosis or on the intestinal wall. The author followed the advice of Bier, who suggested that the mesocolic opening could be fastened either to the wall of the stomach or to the intestinal wall. That the latter procedure may cause complications the author illustrates by a case in which an intestinal obstruction developed, which necessitated a second operation. He cites similar cases from the literature and emphasizes once more that fastening the mesocolic opening to the intestinal wall may have serious consequences. He also advises against fastening on the anastomotic suture and he recommends von Hacker's original method; namely, fastening on the wall of the stomach.

New Indications for Calcium Therapy in Gynecology. E. Wilser.—p. 674.
Simultaneous Bilateral Tubal Pregnancy. F. Heymann.—p. 678.

**Acceleration of Biologic Pregnancy Reaction.**—Hirsch-Hoffmann shows that the action of the hormones A and B of the anterior hypophysis is in some instances already noticeable after twenty-eight hours, but always after thirty-six or thirty-eight hours, provided the quantity injected was sufficiently large. The indication for the presence of the hormone A is the growth of the follicles with formation of a follicle cavity. The cells of the stratum granulosum are somewhat proliferated but do not differ essentially from those of a resting follicle. Presence of hormone B is indicated by a marked enlargement of the cells of the stratum granulosum, which gives the follicle a honeycomb appearance, and also by beginning or advanced luteinous transformation of the cells of the stratum granulosum. The enlargement of the cells the author considers as beginning transformation and in the Aschheim-Zondek reaction he considers it as indicative of an existing pregnancy. He thinks that for the diagnosis of a normal pregnancy it is not necessary to use the most rapid method. However, it should be considered that in urgent cases it is possible to detect signs of pregnancy after thirty-six or thirty-eight hours.

**Induction of Labor.**—According to Hellendall, the effect of Kiwisch's hot vaginal douche is due not so much to the thermic stimulation as to the dilator effect. To effect dilatation, efforts should be made to produce stasis of the fluid in the vagina, which is done by temporarily closing the vaginal opening. Every douche is continued for from one-half to one hour so that the vagina is irrigated by from 50 to 100 liters of fluid. The author cites twelve cases from the literature in which labor was induced by employing only this method, and reports one case of his own observation, in which he had good success by combining the vaginal douche according to Kiwisch's method with Stein's method of injection of solution of pituitary. He reports five other cases in which he induced labor by this combination method and then he describes four cases in which this procedure proved helpful to accelerate the process of labor after the uterine contractions had become weak or had ceased entirely.

*Passage of Brucella Melitensis-Abortus Through Normal Skin of Guinea-Pigs and Rabbits. V. N. Makkaveiskiy, I. V. Karkadinovskaya, N. I. Mixeev.—p. 72.

**Flocculating Property of Antibacterial Serum.**—Elisuiskiy performed flocculation and precipitation tests, according to the methods of Ramon and Deyer, and also complement fixation tests on the meningococcus, Pfeiffer bacillus, Brucella melitensis, and Bacillus anthracis. Tests were performed with fresh serums, some preserved with 0.5 per cent chloroform and others kept at icebox temperature as long as two years. The flocculations of antibacterial serum and filtrates of cultures were in all cases similar to those reported using antidiphtheria serum. The specificity of the flocculation tests was controlled by using normal and nonspecific serums. The intensity and rapidity of the flocculation was found to vary with the serum, the bacterial filtrate and especially with the proportion of each. Ignorance of the latter results in flocculation with characteristic gradual increase in precipitation but no zone of flocculation. Antibacterial serum is stronger than antitoxic serum. The antibacterial serum in contradistinction gives an "initial flocculation," since it contains the optimum of the reacting ingredients. The titer as well as the time for the appearance of the initial flocculation varies with the character as well as the immune property of the serum. Therefore initial flocculation is a good evaluation of antibacterial as well as antitoxic serums. And to obtain a zone of flocculation it is necessary to find the proper proportions when mixing the serum and the filtrate. In studying the zone phenomena, a constant amount of precipitin (serum) should be added to progressive quantities of precipitinogen (bacterial filtrate). In some tests it was noted that the zone of initial flocculation coincided with the complement fixing dose. In others in which this was not true, the author believes that previous flocculation had rendered the serum less sensitive. He concludes that initial flocculation should be a criterion in the determination of immune substances in serums and that it could be added to or used instead of agglutination and complement fixation tests.

**Injection of Bivaccine (Typhoid and Paratyphoid B).**—Budakov and his co-workers in an epidemic of typhoid in 1931 utilized a bivaccine of Bacillus typhosus and Bacillus paratyphosus B. Three variations were included; namely, (1) the usual vaccine consisting of 1 cc. (1 billion typhoid and 500 million paratyphoid bacilli), (2) a formaldehyde treated bivaccine (anavaccine), and (3) a bivaccine in chocolate tablet form (administered by mouth), each tablet containing 100 billion bacilli (two thirds typhoid bacilli and one third paratyphoid B bacilli). Among 7,300 persons, 526 persons were treated with anabivaccine and 3,964 persons were treated with enterovaccine. Serologic examinations for immunity were made in 680 instances: 202 immunized with bivaccine, 162 with anabivaccine, 207 with enterobivaccine, and 109 controls without immunization. It was found that most of the high titers were due to bivaccine in spite of the fact that less of the antigen was used for vaccination; and the number of negatives for both typhoid and paratyphoid were less. The titer for Bacillus typhosus was always higher than for Bacillus paratyphosus B. The negative serologic reactions were between 40 and 50 per cent, and the titers were lower for both typhoid and paratyphoid when the enteral route rather than the subcutaneous route was used for immunization. The authors conclude that the bivaccine gives better results than the anavaccine and that the subcutaneous route is preferable to the enteral route.

**Influence of Bacteriophage on Local Infections.**—Sharov discusses two series of experiments in which bacteriophage "Posen" was used for treatment. In one series the articulations of a number of mice were experimentally infected with the paratyphoid B bacillus, and this series received for treatment subcutaneous injections of bacteriophage. Similarly another series of mice with experimental local infectious processes received intravenous injections of bacteriophage. The mice were killed after seventy-two hours and cultures were made of the articulations, blood, and lymph nodes. The author found that in spite of the fact that the bacteriophage strain "Posen" produced lysis in high dilutions when brought in contact with Bacillus paratyphosus B in vitro, his experiments showed no decrease in the microbic flora when the experiments were performed in vivo.

**Electrophoresis in Study of Rabies Virus.**—Gluzman and his co-workers used emulsions of brain from rabbits infected with rabies and killed in the agonal stages. The emulsions were diluted 500 times in buffers ranging from $p_H$ 6.0 to 9.3. The apparatus for the electrophoresis was a modification of Todd's instrument. The current at the rate of from 0.8 to 7 milliamperes with a potential of 120 volts was allowed to flow from two to sometimes three hours and then quantities of solution were taken from the region around the positive pole and around the negative pole and for control purposes from the region in between the two poles, and rabbits were injected subdurally. No change in virulence for rabbits was noted in the material taken during the passage of the current. The solution taken from the anode was virulent in twenty-one of the twenty-seven instances. The solution around the cathode was virulent in six instances, but in the latter the solution around the anode proved to be virulent at the same time. The range of hydrogen ion concentration in the six instances was from $p_H$ 8.0 to $p_H$ 8.6 and the rate of movement was slowest in that range. The authors conclude that the electrophoresis of the rabies virus is toward the positive pole in the $p_H$ range of from 6.0 to 9.3. The virus loses its virulence on the acid side or at the iso-electric point. It was not found possible to separate the virus from the rest of the solid substance.

**Passage of Brucella Melitensis-Abortus Through Normal Skin.**—Makkaveiskiy and his co-workers state that the alimentary tract is not the only portal of entry for Brucella abortus and Brucella melitensis. The skin as a portal of entry was used in two groups of guinea-pigs (twenty each) and two groups of rabbits (ten each) in experiments on Brucella melitensis and Brucella abortus. In ten rabbits and ten guinea-pigs, the injections were made into the conjunctiva. The authors found that agglutination tests were positive in 25 per cent of the guinea-pigs and 60 per cent of the rabbits infected through the normal skin with Brucella abortus; and the tests were positive in 10 per cent of the guinea-pigs and 20 per cent of the rabbits infected through the normal skin with Brucella mellitensis. The tests were positive in 60 per cent of the guinea-pigs and 90 per cent of the rabbits injected with both strains into the conjunctiva.

## Ugeskrift for Læger, Copenhagen

### 94: 249-278 (March 10) 1932

*Diagnosis and Prognosis in Cardiac Diseases. E. Warburg.—p. 249.*
Ulcer of Leg and Treatment. H. Tvedegaard.—p. 256.
*Hematologic Casuistics. K. Winge.—p. 259.
*Albuminuria in Polycythemia and Relation During Treatment. H. C. Gram.—p. 262.

**Hematologic Casuistics.**—In Winge's first case, of acute leukemia, epistaxis was the earliest symptom and death occurred after barely three weeks. The second case, of myeloid leukemia, was in a patient aged 76, with a history of recognized symptoms for only six months. In the third case, of lymphosarcoma, there was a moderate anemia with lymphocytosis, followed after roentgen treatment by lymphopenia. The fourth and fifth cases illustrate the varying pictures in the development of a pernicious anemia, with, in the last, difficulty in diagnosis.

**Albuminuria in Polycythemia.**—On the basis of three cases of polycythemia treated with phenolhydrazine and benzene, Gram is inclined to believe that the albuminuria in polycythemia may be a result of the increased number of cells, not the cause or a coordinated phenomenon. The albuminuria, he says, is improved or disappears when the blood values approach or attain normal values as the result of effective treatment.

*Infectious Mononucleosis. A. Nyfeldt.—p. 279.
Dependence of Normal Kidney Function on Size of Body. C. Holten.—p. 288.
*Blood Sugar Studies in Diphtheria Patients. A. Brems.—p. 292.
Two Cases of Recurring Measles. K. Lau.—p. 298.

**Infectious Mononucleosis.**—Nyfeldt describes the history, clinical aspect, diagnosis and differential diagnosis of this condition, partly from study of the literature. He urges examination of the blood in all diseases of the throat in order to make sure the diagnosis, particularly for the timely diagnosis of agranulocytosis.

**Blood Sugar Studies in Diphtheria Patients.**—Brems says that a moderate fasting hyperglycemia is not infrequently seen in the acute toxemic stage of diphtheria. The blood sugar curve after oral administration of 1 Gm. of dextrose per kilogram of body weight in many cases of only fairly grave diphtheria shows remarkably high maximal values and a strongly protracted hyperglycemia, with return to normal usually after from one to two weeks. The phenomenon is due to the intoxication, being frequently noted in afebrile patients and absent in mild cases with possibly considerable rise in temperature. At the start of the condition, glycosuria is occasionally seen. After the administration of dextrose, the elimination of sugar in the urine is an almost constant phenomenon in toxic patients.

VOL. 98, NO. 25 CHICAGO, ILLINOIS JUNE 18, 1932

# DRUG ADDICTION—A WORLD-WIDE PROBLEM

PAUL WOLFF, M.D. PH.D.
*BERLIN, GERMANY*

The pursuit of intoxication, the search for a means of invoking a condition of unimagined bliss, though it be but a bitter self-deception, a paltry fool's paradise, is a goal which even the most primitive peoples have sought and found. At all times and in all places, in the days of Homer, under the tropical sun and in the regions of eternal snow alike, mankind has found methods of attaining this "holy," god-given madness. So long as narcotics remained the secret of the priesthood, they were of little danger to mankind in general. In more modern times, the explanation and popularization of hitherto sacred usages, the expansion of science, the extension of our knowledge and experience and, above all, the enormous advances made in the last hundred and fifty years in the medical and natural sciences have brought about a change. A few of the milestones in the development of medicine include the isolation of morphine by Sertürner in 1806, the ingenious invention of its subcutaneous injection in 1853 by Wood, whose first experiments on injection were carried out with a solution of morphine, and the introduction into medical practice of cocaine, the anesthetic properties of which were known in 1860 but which curiously enough was not used therapeutically until Koller, a Viennese physician who found his second home in the United States, first employed it clinically in 1884. This triumph of rational therapy based on the results of experimental and clinical research had, however, its darker side in the growth and extension of drug addiction. Among the many bitter legacies of the World War and postwar times, not the least difficult to combat was this scourge. New problems constantly arose to be solved. As a result, many medical and social questions were once again revived or brought into greater prominence. Through careful scientific investigation many phenomena, for instance the rapidly increasing incidence of cocaine addiction, took on a new aspect. Older problems were examined in a fresh light and were measured by newer and more rational standards.

Drug addiction is a colorful picture of varied perspective. In this field practical medicine must work in the closest possible collaboration with legislation and justice in order that useful progress may be made, in the interest not only of individual patients but also of the health and sanity of the race as a whole. The economist, too, should have his place in the council chamber, for drug addicts are not only a source of leakage from the ranks of producers and consumers but also a permanent burden on the national exchequer.

It is hygiene, in the best sense of the word, that must here be practiced. From the physician it demands much effort and knowledge and a full sense of responsibility. He must not be beguiled by false sympathy into prescribing habit-forming drugs to individual addicts. It is his special duty to institute a withdrawal cure and thus perform his part in freeing the world from a plague which in many places has become an epidemic. Should the term epidemic seem too bold, it is only necessary to consider how many members of our own profession in every country have been attacked by the "virus" of drug addiction; how many meritorious physicians and research workers in this field have succumbed to its seductive influence in spite of all their knowledge and, one hesitates to say it, by a seemingly irresistible chain of events, have found in it their ruin.

A few figures will suffice to support this disturbing contention. Out of 100 male morphine addicts, Oppenheim, the late Berlin neurologist, found in prewar times 42 physicians, the Munich psychiatrist Kraepelin 10 out of 42 addicts, and E. Meyer 21 out of 64 addicts, apart from members of associated professions, such as nurses and dispensers. Similar figures are given by other clinicians. In postwar times the percentage of the total number of addicts represented by medical men has considerably decreased but it is nevertheless still high enough. According to recent statistics (1928) the number of physicians in Germany who personally consume a tenth of a gram or more of morphine daily is about 500; that is to say, roughly 1 per cent of the profession.[1]

The medical addict forms a source of danger in that his addiction may lead him to prescribe his favorite drug too lightly for his patients without exercising rigorous judgment from the medical standpoint as to the real need for it. Such a condition is not far removed from proselytism, and the physician who no longer fully realizes the sacred nature of his professional responsibility may form the nucleus of a colony of addicts, quite apart from the so-called script doctors, who have shown themselves entirely unworthy representatives of our profession. At this point, however, it is necessary to emphasize the fact that there are many physicians of high standing and worthy achievement who are to a certain extent morphine addicts but who nevertheless carry out their duty in every possible way and who prescribe opiates and cocaine solely in accordance with the strictest rules of medical practice. Apart altogether from legal procedures connected with

transgressions of the law, it is necessary in all countries to introduce a system whereby those physicians whose addiction has rendered them dangerous to the community should be deprived of their licenses; such a regulation will shortly be enforced in Germany.

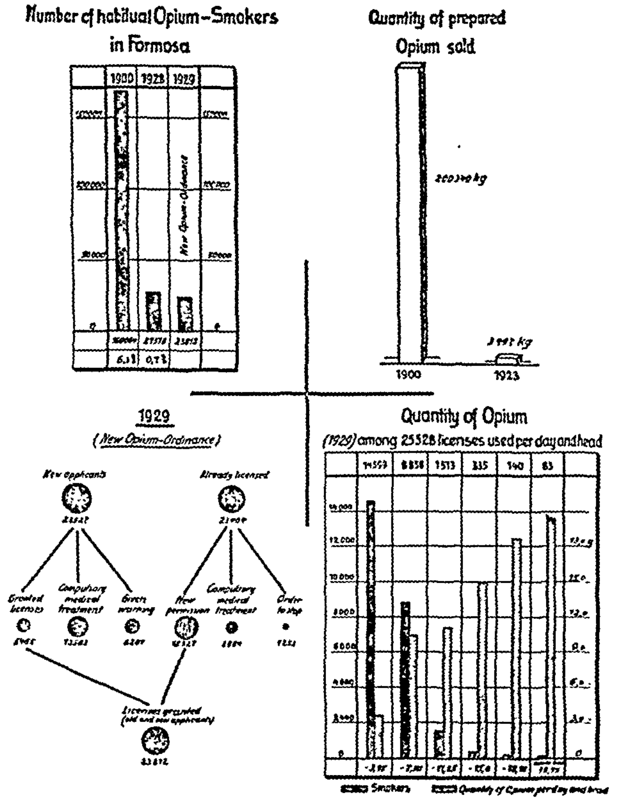

Fig. 1.—Opium in Formosa.

NARCOTIC ADDICTION THROUGHOUT THE WORLD

In order to demonstrate clearly the universal nature of the problem of drug addiction, it is necessary to review briefly the situation in various countries. It is not easy to make a selection but I must of necessity content myself with the description of only a few scenes from the world panorama. For the present purpose, therefore, I will briefly outline the conditions in China, Formosa, British India and Egypt. Of the European countries, Germany will be particularly discussed.

In 1907 the hope was cherished that it would be possible over a period of ten years to obliterate entirely both the internal production in China itself and the importation of opium from India, so that in 1917 the problem would have been in a large measure solved. In the meantime, however, internal political changes have taken place which are today occupying the attention of the whole world and which permit the continued existence of the opium scourge. We are not concerned here with political questions except so far as they concern narcotic addiction. While the cultivation of opium is technically forbidden, the army continues to demand it. According to what one reads and hears, many of the Chinese military authorities of the most various political parties are themselves extensive dealers in opium and the legally introduced fines have degenerated into a system of licenses. In addition, a severe abuse of morphine has arisen in the distribution of diacetylmorphine. It has been observed that the Chinese soldiers roll themselves cigarets from tobacco with which diacetylmorphine powder is mixed. The coolies preferably submit to an injection of morphine, since this produces the desired effect more quickly and cheaply than the smoking of opium, which takes up much more of their working hours. The placards of the Chinese Anti-Opium Association are eloquent, but the campaign seems to be somewhat too idealistic and at present bereft of any great effect in the desired direction. The restoration of political stability within the country itself would undoubtedly lead to better conditions. Chinese physicians who have studied in European or American universities are entirely in agreement with our attitude toward drug addiction.

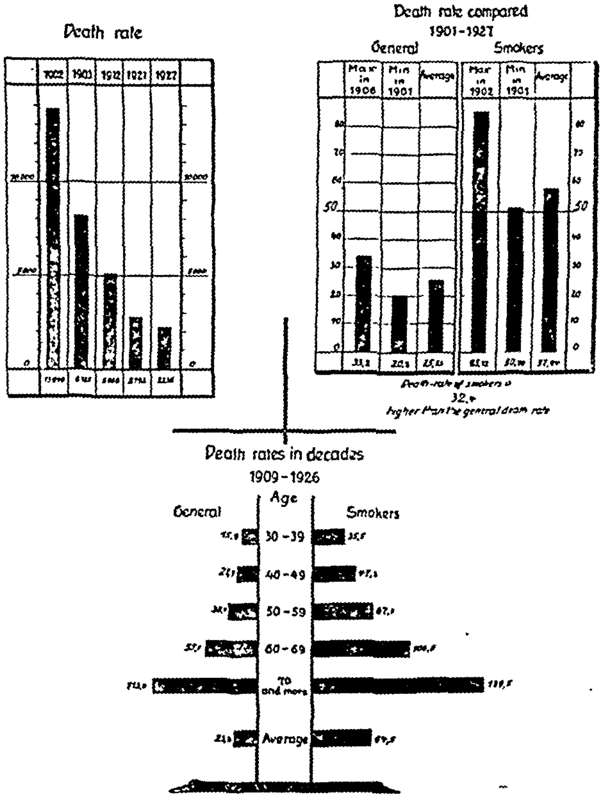

Fig. 2.—Death rate among opium smokers in Formosa.

As a contrast to the indefinite position in China, it is interesting to note the gradual reclamation of a Chinese population in the island of Formosa,[2] which is under Japanese control. In this territory, certain sections of the population are granted a license to smoke opium and the individual smokers are controlled. A complete census has been maintained and, as will be seen from figure 1, the number of smokers reached 6.3 per cent of the population in 1900 and 0.7 per cent in 1928; that is to say, it has been reduced to one ninth in twenty-eight years. Parallel with this, the amount of opium sold for smoking purposes has been reduced to one sixtieth of the former consumption. In 1929 a new opium ordinance was issued and the old applicants for licenses were sifted out from the new and hitherto unlicensed candidates. It will also be noticed (fig. 1) that a considerable number of new applicants were obliged to undergo a compulsory "withdrawal" cure, Formosa being the only country where such a measure is legally enforced. From the old applicants, although the majority received new licenses, some were refused permission to continue opium smoking. Further, others were warned off, so that the combined number of old and new applicants was roughly the same as the number of previous license holders, instead of showing an increase to twice this figure. In addition, it will be seen that the majority of smokers get along with a minimum quantity of opium and that appreciable quantities are allowed only to a rapidly diminishing number of addicts. It may be of interest to compare these figures with American experience in the reformation of another island, the Philippines. The fact that the death rate among opium smokers is much greater than the average for the same population is borne out by the literature (fig. 2). The mortality among smokers is in fact 32 per thousand higher than the general death rate, and this relationship is essentially similar throughout the various age periods. The origin of opium addiction in the lowest social strata is in large measure due to the fact that here, as in other Asiatic countries, opium is considered as a "home remedy" (fig. 3). Nevertheless the euphoric effect undoubtedly plays a certain part.

[2] Commission of Enquiry into the Control of Opium Smoking in the Far East, League of Nations, Geneva, 1930, volume I. Tu: Statistical Studies on Opium Addiction in Formosa, Jap. J. M. Sc. Tr. IV, Pharmacol. 5: 48-52, 1931.

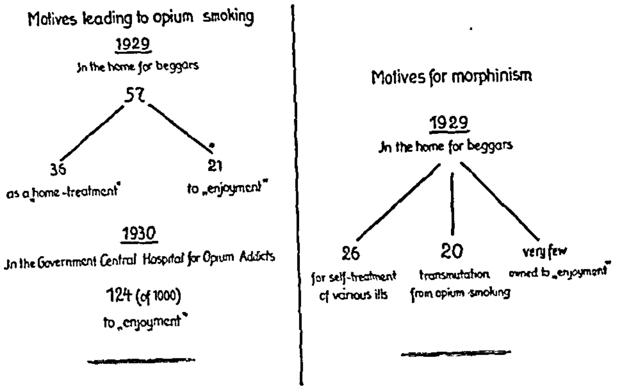

Fig. 3.—Motives leading to opium smoking and to morphinism in Formosa.

It is curious that in another closely related population, namely, the Japanese, addiction is unknown as a national practice.

In British India opium eating is also endemic[3] although, as far as we know, it is decreasing rapidly, at least as far as the production of the drug goes. A stringent control is being exercised, which, however, is largely vitiated by the fact that the semi-independent native states have preserved their independence in this respect. Since 1926, public auctions of opium in Calcutta have ceased to take place. According to a resolution of the government, the export of opium to the Far East, apart from supplies destined for medical or scientific purposes, will have ceased within ten years; that is to say, at the end of 1935. So long, however, as opium is manufactured in quantities far in excess of those required for these serious purposes, the prevention of illegal traffic is impossible. At the same time the retail prices have been raised, a measure which will perhaps also contribute to the suppression of the habit. A more serious and, medically considered, incredible fact is the Indian mothers' custom of giving opium to their children to prevent them from crying and to insure that they sleep and are quiet while the mother is at work; further, opium is held in such high esteem that it is administered to children with the intention of rendering them fat and strong! The superstition that centers around the poppy juice forms a great obstacle to its removal, as do many other external factors which can be fought only with difficulty. A nation will not readily give up a household remedy.

Curiously enough, opium smoking is not customary in India. On the other hand, a certain special form of addiction is practiced which, as far as I know, is peculiar to India. It consists of the use of the intact capsules of Papaver somniferum—the so-called "post." This practice is confined to the Punjab, where there is a total of only 6,500 addicts. The fresh poppy heads are thoroughly macerated with water and the resulting fluid is swallowed. In contradistinction to opium addiction, "post" is preferably taken in company with others, and among the lower classes "clubs" exist for this purpose. This form of opium consumption is cheaper and is not subject to control. It exists solely as a habit, and is not used medically. The effect, which appears in some twenty or thirty minutes, is said to be more markedly euphoric than that of opium eating. The morphine content of the liquid is relatively small in relation to the larger quantities of narcotine, codeine and papaverine that it contains. To a certain extent this beverage is used as a "household remedy," though never in serious illness. It is far more popular as a "society drink" as a euphoric and as a substitute for alcohol among manual workers. I have described this unusual form of addiction in some detail since, in spite

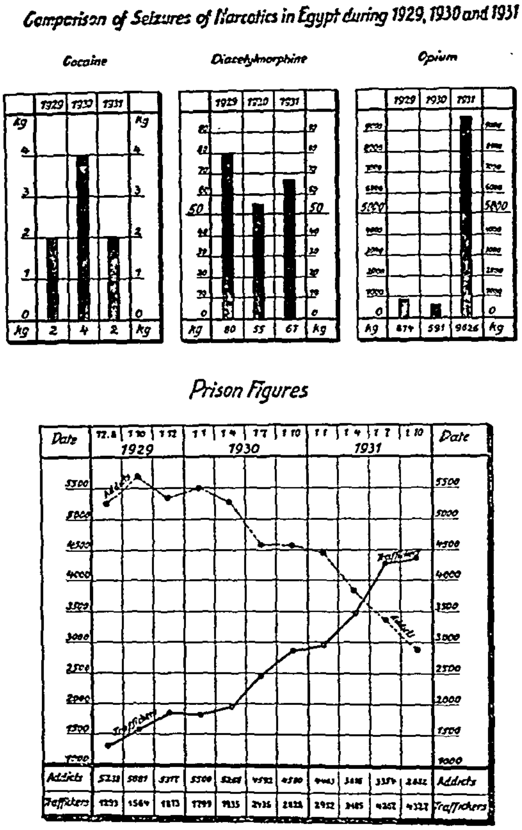

Fig. 4.—Narcotics in Egypt.

of its limited occurrence, it represents an interesting divergence from the usual methods of opium consumption. The effect is weaker and of shorter duration, as might be expected from its composition. It is more an excitant than a sedative and has a less marked effect on the alimentary tract. It has a more pronounced diuretic action and a certain restorative effect. The addicts show pronounced loss of memory, and in spite of the small morphine content considerable physical, mental and moral degeneration sets in. While an opium addict taking small doses may not be easily differentiated from a normal individual, a person taking even small quantities of "post" at once gives himself away—so much so that in the Punjab a lazy, slovenly, dull and unintelligent-looking person is often called a "posti." The results of abstinence recall to a great extent those observed with opium withdrawal. The habit becomes deeply ingrained. "Post" addiction thus forms an interesting variation in drug addiction which is fortunately not widely spread.

Finally, a glimpse into the conditions existing in a part of North Africa, Egypt.[5] The cradle of civilization has become the chief battlefield in the fight against the trade in illegal drugs. Russell Pasha, the chief of the Cairo police, recently stated that among a population of 14 millions, there are, at a moderate estimate, some half a million addicts. This figure includes, however, the many hashish smokers, the total number of whom, however, appears to be rapidly decreasing as a result of the energetic measures directed against the practice. While all classes of society suffer from the scourge, it is chiefly the poorer classes who are involved. In the central prison there is at the present time a constant population of some 7,000 addicts and dealers sentenced for participation in drug traffic. In all necessary cases these prisoners receive medical treatment in the form of withdrawal cures. It is interesting to note from figure 4 that, while the number of addicts has fallen considerably, the number of dealers has risen.

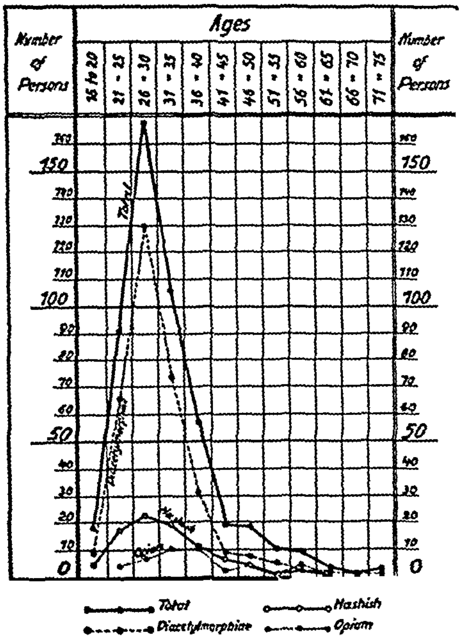

Fig. 5.—Ages of 500 prisoner addicts in 1931 in Egypt.

Whereas in two years the number of persons convicted for trafficking has increased nearly threefold, the number of persons sentenced for addiction has fallen by 50 per cent. The same causes as in 1930 have been helping in 1931 to bring about this reduction in addiction: adulteration is so high that dope is hardly worth buying, and money is so scarce that the fellahs can no longer afford to waste it on drugs that give no kick.

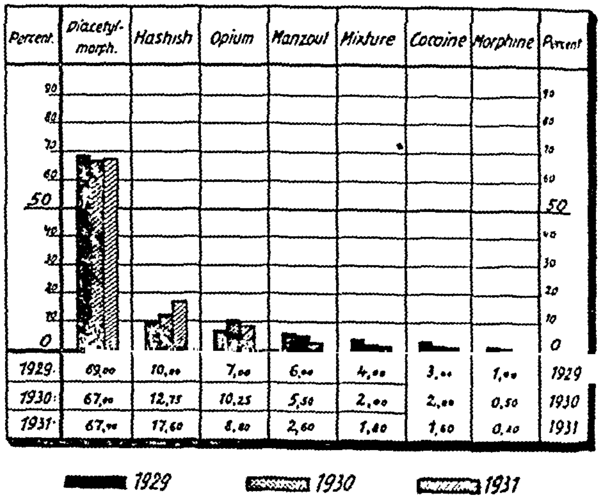

Fig. 6.—Drugs to which 200 Egyptians in 1929, 400 in 1930 and 500 in 1931 were addicted. Manzoul consists of a mixture of hashish, dry spices and herbs.

The effectiveness of the methods of control will be obvious from figures 4, 5 and 6, from which it will also be seen that diacetylmorphine plays by far the most important rôle, while the success of the measures against opium consumption is equally evident. In this country cocaine is only of slight importance. Diacetylmorphine is particularly favored by Orientals as it is thought to be an excellent aphrodisiac, though actually it exercises this effect only in the earliest stages of addiction.

Hashish is again becoming a big problem. This increase of hashish smuggling (from Syria, further supplies are now being smuggled in from Turkey and perhaps Yugoslavia) is, however, a clear sign of the increased difficulties in obtaining the white drugs. I believe that figures 4, 5, 6, 7 and 8 give a clear indication of the situation today in Egypt. Addiction to white drugs, though still terribly prevalent, is not as widespread as before. Hundreds and thousands of people, possibly formerly honest, have been tempted into trafficking by the profits to be made and are now paying the penalty. This illustrates that the damage done to a country by drug addiction is not merely the medical damage done to the addicts but is the much more serious harm done by the widespread corruption introduced by it into all classes of society.

The remaining charts confirm the experience gained in our own territories. The majority of addicts are in the prime of life; i. e., from 20 to 40 years of age, although children of 11 to 15 and even 6 to 10 years are also found. Addiction lasts as a rule from two to five years. As before stated, diacetylmorphine occupies the most prominent position, a point also borne out by analysis of the various age decades.

A further improvement in the conditions is to be expected, now that Turkey has at last introduced a control of internal production. It has been subsequently shown that enormous quantities of diacetylmorphine were manufactured in Turkey, the export of which not only to Egypt but also to Europe and the United States was attempted.

---

[5] Egyptian Government, Central Narcotics Intelligence Bureau, Annual Report for the years 1929, 1930, 1931. Wolff (footnote 10).

It will thus be seen that there are many strongholds of the drug traffic and of drug addiction which remain to be seized. The front line of attack against these fortresses must be occupied by the medical profession.

As to the position in Europe there is little to add. According to our present knowledge, the general impression is that addiction is in all respects on the decline. Occasional cases of smuggling on a large scale, which provide sensational reports for the daily press, need not deter the physician from arriving at this conclusion. Great Britain, for instance, has exceptionally few alkaloid addicts, a fact of which I am constantly receiving fresh confirmation. Drug addiction has for her ceased to be an acute problem and conditions are probably much the same in Norway, Sweden and Denmark. As to the position in France there is little information. At the present time scientific investigations in this field are being carried out chiefly in the German speaking countries. The new Austrian legislation is unfortunately all too lenient, with the result that Vienna has become a center of smuggling. The Egyptian government has recently protested against this state of affairs. Thus, once again the close interdependence of the various countries is emphasized and the universal nature of the problem of drug addiction demonstrated.

### THE SITUATION IN GERMANY

In Germany the number of addicts has unquestionably greatly declined, as is shown by the decrease in the number of morphine and cocaine addicts arrested in public resorts (fig. 9). According to exact calculations made in 1928, the number of addicts, so far as the needs of these individuals are covered by medical prescriptions, varies from 4,000 to 6,000 in a total population of about 64 millions.[1] Through the "opium department" of the health office of the *reich* (reichsgesundheitsamt) it is possible for the government to obtain an extensive survey of the whole traffic in these substances and to exercise a control over prescriptions. Somewhat more than a year ago a decisive step forward was made. In full agreement with the German medical profession, the government has introduced a system of stringent restrictions:[6] Before ordering any substance covered by the German opium law (drawn up in accordance with the international convention), every physician is in duty bound to ascertain whether, according to the strictest medical principles, the prescription of the drug is definitely necessary.[7] The handing over of the substance itself is absolutely forbidden, and a pharmacist is not allowed to make up a prescription containing more than one opiate. Further, all these substances may not be present in a mixture in more than a certain percentage. For each patient, up to 0.2 Gm. of morphine may be prescribed daily without further formalities, provided the form of the prescription complies exactly with the prescribed regulation. A corresponding quantity of opium (2 Gm.) and the galenic preparations, particularly tincture of opium, is allowed. A similar amount is also allowed for general daily use in the physician's practice. The pharmacists do in fact observe these rules closely. Should the physician require larger quantities for "special cases," he must make an entry in the so-called morphine book.[8] The nature of the disease rendering such quantities necessary must be precisely stated and the period of time for which the remedy is prescribed. As in most cases the patient will be an addict, the numerous questions which the physician must answer in writing in the morphine book are specially adapted to drug addiction. The questionnaire reads as follows:

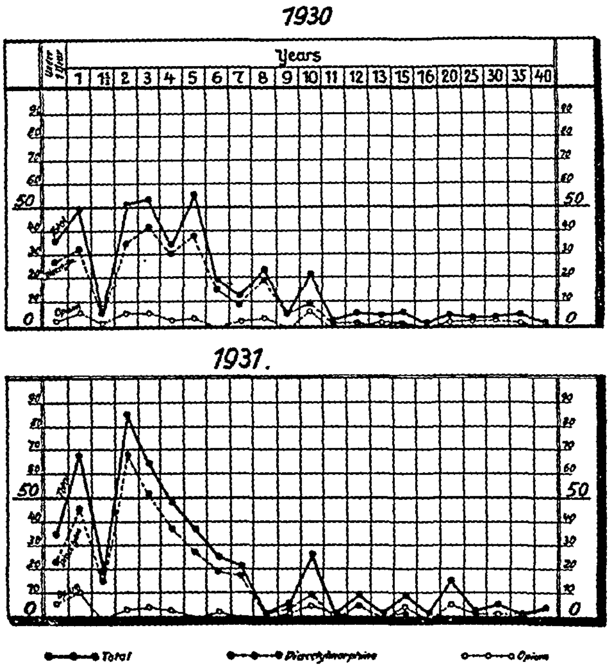

Fig. 7.—Duration of addiction of 400 Egyptian prisoners in 1930 and of 500 in 1931.

| *Age* | *1929* | *1930* | *1931* |

[8] Wolff (footnote 6, third reference).

Codeine and ethylmorphine hydrochloride are not practically dangerous from the point of view of habituation and, like papaverine, do not come under the German opium law.

On the other hand, the newer synthetic substitutes for morphine, which are also fundamentally habit forming, are included in that they may be prescribed only in certain amounts per patient daily. I would like to emphasize especially the fact that diacetylmorphine plays an extremely insignificant part in German medical practice and it is a matter for congratulation that it is little used by drug addicts. In this case the amount that may be legally prescribed, viz., 0.003 Gm. daily, is particularly low. If at any time it should be decided to demand the complete abolition of this preparation in the world, the slight advantages of which are by far outweighed by its disadvantages, I am firmly convinced that no opposition would be encountered from the German medical profession. More resistance would appear to be forthcoming, however, from English and French physicians, who employ small doses of diacetylmorphine to a much greater extent. This divergence of opinion was clearly perceptible at the last conference held by the League of Nations in Geneva on the limitation of the manufacture of narcotic drugs, in June, 1931.[9] Here the American delegation expressed its entire agreement with our expert attitude toward the complete suppression of diacetylmorphine. An advance was, however, made in that it is proposed to institute a special control over the traffic in diacetylmorphine between the individual countries. It is to be hoped that these restrictions will serve to convince the medical profession in countries where diacetylmorphine is still used that the drug is in no way indispensable. The recommendations appended to the minutes of the convention read as follows:

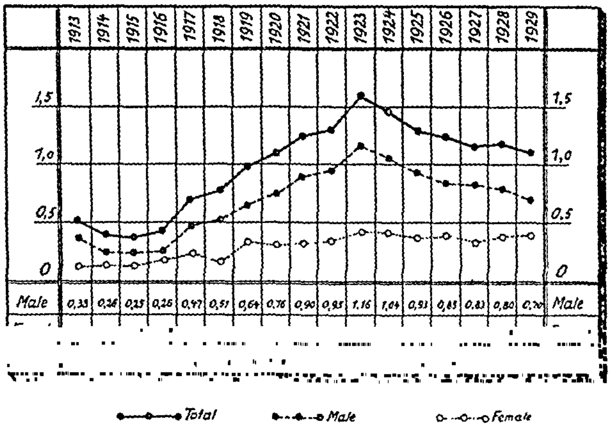

Fig. 9.—Percentage of addicts received in public mental hospitals of Prussia.

> The Conference:
>
> Recognizing the highly dangerous character of diacetylmorphine as a drug of addiction and the possibility in most, if not all, cases of replacing it by other drugs of a less dangerous character:
>
> Recommends that each government should examine in conjunction with the medical profession the possibility of abolishing or restricting its use, and should communicate the results of such examination to the secretary-general of the League of Nations.

This resolution undoubtedly constitutes a step forward in the task of suppressing this substance.

It appears to me to be of importance to give a brief outline of the other most important substitutes, without going into the details of chemical composition. It is sufficient to state that in their chemical constitution they are all closely related to morphine and are capable of giving rise to addiction. Dihydro-oxycodeinon, the oldest of the substitutes, has a marked narcotic and analgesic action. It has all the properties of morphine and is often better tolerated by sensitive patients. At times, however, it exercises a potent euphoric action which is frequently undesirable. In this connection, however, it should be emphasized that in many hopeless cases of carcinoma and tuberculosis it is essential to administer morphine or some other opiate as a euphoric. Addiction to dihydrocodeinon is not to my knowledge very common, on account of the fact that it is generally given orally rather than by injection. It frequently produces a very marked and desirable codeine effect. Dihydromorphinon has also proved valuable. It is often better tolerated and has the particular advantage that it depresses peristalsis less than morphine (hence its use after abdominal operations). Further, it has been shown both experimentally and clinically that it leads more slowly to habituation and addiction and its devotees are therefore more easily cured.

A further great advance would be made if injections of morphine, and the like, were replaced as far as possible by the use of suppositories. Not only do these produce the same qualitative and quantitative effect but also the patient is not immediately aware that he has received morphine. In many cases in which medical treatment is the origin of the addiction, numerous mental associations would be avoided in the absence of the symbol of the syringe. For example, after abdominal operations the routine use of a certain number of morphine injections is objectionable. A suppository will produce precisely the same result and, in addition, the syringe will thus be taken out of the hands of the nurse a most desirable achievement.

The strict control over the prescription of opiates, which has been described, has had its visible result in the great decline of the use of such drugs within the country. The consumption of morphine has decreased from 1,350 Kg. in 1925 and 1,600 Kg. in 1926 to 1,160 Kg. in 1930. Although the exact figures for 1931 are not yet available, a further fall of about 25 per cent is expected. Opium has similarly fallen. In 1931 some one third of the previous figure of 2,600 Kg. was used, a diminution of two thirds. The employment of diacetylmorphine in Germany has for some time been very limited. From 50 Kg. in 1925 it sank to 38 Kg. in 1930, and the figure for 1931 will be about 66 per cent less, a very small amount indeed, which need hardly be considered for practical purposes. All things considered, the sacrifices to which the medical profession has submitted have produced a marked decline in the use of habit-forming drugs.

In comparison with our experience in the war and postwar periods, cocaine addiction no longer presents a grave scientific problem. Here again I feel justified in considering the details of special pathology and therapy as well known.[10] With our present accurate knowledge of the features of the disease, it is impossible to understand that in the eighties cocaine was seriously recommended and employed for the treatment of morphine addiction and that a military physician was prompted to recommend cocaine as a method of improving the marching capabilities of soldiers. Today the uncritical praise that was accorded to cocaine in the medical literature of almost every country must be discounted. The reaction of critical and far-seeing medical men rapidly set in and the story of morphine-cocaine addiction is now only a painful memory.

I should like to refer briefly to one point in the pathology. The question of the exact relation between pure cocaine addiction and homosexuality[11] does not appear to be entirely clear. That such a relationship exists is clear from the observations of a number of experienced research workers. I have seen such cases in which, while exercising all possible critical judgment and scientific caution, it was possible to say that at any rate the homosexual activity first appeared during the period of cocaine abuse. Today we know that the female sex hormone is also present in the male organism and this fact tends to confirm what appears to me to be the most likely explanation of this phenomenon. It may well be that sexual impotence, which occurs in men as a result of cocaine addiction, brings to the surface a hitherto latent component of inversion, the degree of which is dependent on the extent to which the individual is bisexual. In this connection it is significant that after a "withdrawal cure" or, better said, after "disintoxication," a certain number of these persons recover complete heterosexuality, while others remain either homosexual or bisexual. I doubt, however, whether this is a true pharmacodynamic effect, and it must not be forgotten that among cocaine addicts it is more common to find persons of somewhat unstable mind and character than among the many types of opium addicts. Among the devotees of cocaine it is common to find unrestrained and psychically labile types of many varieties which are summed up under the somewhat vague name of psychopaths. On this point much remains to be cleared up, but from the medical point of view it would perhaps be more satisfactory if the problem remained unsolved owing to the dearth of clinical material resulting from the rapid decline of cocaine addiction. I myself am optimistic and I hope to be able to justify this attitude by showing the rapid and energetic measures which we are taking to combat cocaine addiction. At any rate, in Berlin it is now a matter of no small difficulty to find a true case of pure cocaine addiction to demonstrate to students.

### THE SPREAD OF COCAINE ADDICTION

A few words must first be said with reference to the spread of the abuse of cocaine. The wave of "snow" or "white powder" (many varieties of pet names for the drug were employed by addicts in various countries) that flowed over Europe during and after the war is now on the ebb. Before the war there was little abuse of cocaine, at least in central and western Europe. There were individuals who employed cocaine injections and also combined morphine and cocaine addicts. The habit, however, of taking the drug like snuff into the nose, which is the outward sign of the spread of the addiction (and which corresponds to the popularization of morphine by the introduction of the pravaz syringe), was not noticeable until the war, when it first broke out in France, in the Russian army and later in central Europe.

What is the method of spread of the abuse of cocaine? The answer to this question appears to me to lie in the known facts with regard to its spread in a country which remained free from war, British India.[11] The habit began by chance in a small provincial town, where a land owner employed cocaine against toothache and subsequently became an addict. The habit was then spread by proselytism, as is common with cocaine among young people. The habit then rapidly spread along the two main railway lines toward northern India, through the agency of commercial travelers and others. Towns on side-lines and the larger part of the country districts have remained free from cocaine addiction, as shown on the map (fig. 10). Many rapidly became the victims of this nefarious trade, which as usual brought in handsome profits. Cocaine was in particular demand among manual workers and other sections of the lower classes on account of its reputation as a sexual stimulant (this, as already stated, is the case only in the early stages of addiction). From an etiologic point of view it is interesting to note that only in a negligible number of cases was medical treatment with the drug the origin of the addiction, a state of affairs which contrasts with the position in Europe and, perhaps, America. Cocaine previously reached India chiefly from Europe and also from America. Since its prohibition it has been mainly obtained from Japan, mostly through the agency of Chinese smugglers. Japan has been engaged in the manufacture of habit-forming drugs for only a comparatively short time, some fifteen years, and there now exists an extensive smuggling organization. Here, as in other countries, such as Egypt and the Far East, a water-proof packet containing narcotics is frequently made up and weighted with a sack of salt. Both of these are thrown into the water and later, when the salt has dissolved, the packet containing the drug rises to the surface and is fished out. The number of cocaine addicts in India is estimated at from a fourth to half a million, most of whom are in the prime of life between 20 and 40 years of age. The extraordinarily wide extension of the addiction does not here depend on the possibility of inhaling the drug as is the case in Europe and America. In India the drug is associated with the chewing of betel nut. The snuff-

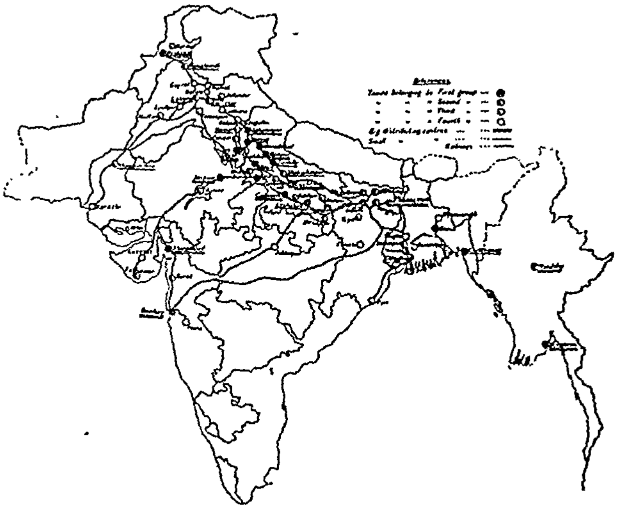

Fig. 10.—Provinces and principal cities in India, in which there is addiction to cocaine.

11. Chopra, R. N., and Chopra, G. S.: Cocaine Habit in India, Indian J. M. Research **18**: 1013 (Jan.) 1931.

ing of the drug is, curiously enough, unknown in India up to the present.

This short account of a state of affairs which is not generally known serves to show that cocaine addiction has also spread with alarming rapidity among a population which differs markedly in many ways from that of Europe and North America. Mohammedans and Hindus are both involved in the habit, the former, however, to a considerably greater extent. Cocaine addiction is thus no less a world problem than morphinism and other opiate addictions.

In all serious consideration, however, it is possible for several reasons to regard the combating of cocaine addiction with greater optimism than is the case with addiction to opiates. Undoubtedly the great increase in the amounts available has contributed to the spread of the addiction, although South America has been ousted from the pharmaceutic market for pharmaceutical cocaine by the cultivation in the Dutch Indies of a coca leaf which has a higher content of the alkaloid. Countries that previously imported their supplies now manufacture the required amounts themselves, as for instance Japan. There are no medical grounds whatever for the justification of increased production and there is no evidence whatever that the amounts previously available in the market were not sufficient for medical purposes. On the contrary! Further, from our point of view, economic and commercial questions can carry no weight against moral and ethical considerations in the province of drug addiction.

The world problem of cocaine addiction resolves itself into the problem of its complete eradication. This is well within the bounds of possibility and, using the German legislation as an example,[12] I purpose to show that in pursuing this aim we are in no sense hunting a phantom. Prevention is here better than cure. For over a year the handing out of cocaine in substance by pharmacists has been entirely forbidden. In this respect we are merely giving practical application to the opinion expressed in the report of the German Medical Congress in 1928, an opinion with which all will surely agree. "It is absolutely unjustifiable for a physician to supply cocaine to a cocaine addict. There is no question of malpractice or of endangering the addict's life associated with the complete refusal to prescribe the drug under any circumstances whatever." Sudden withdrawal is, on the contrary, the treatment of choice.

The largest amount with which any physician may be supplied for daily use in his practice is 1 Gm., and this may be issued in at most a 10 per cent solution. When prescribing it he must make out a very accurate prescription and make a corresponding entry in the so-called cocaine book.[9] He is allowed to use this solution for operations (including diagnosis) only on the eye, larynx, nose and ear and for surgical attacks on the pharynx and maxilla. Further, it may be applied only to the mucous membrane. Any form of injection is forbidden, as also its use in internal medicine (as for instance in the treatment of painful gastric ulcer or in urology) except to a small extent; for example, the use of a 1 per cent solution with the addition of at least 0.1 per cent of atropine sulphate is permissible for nebulization in bronchial asthma. Many experts in the various branches of medicine were consulted and they were all of the same opinion. In addition, the physician may provide the patient with small amounts not exceeding 0.1 Gm. daily, for home use. Full details must, however, be entered and only a 1 or 2 per cent solution should be used. On this point the full agreement of the profession was obtained. Before the new ordinance, a large proportion of smuggled goods were obtained by prescriptions without the knowledge of the physician, through miscalculations. Apart, however, from such cases, which are exceptions, we were convinced that the consumption of cocaine was fundamentally susceptible of limitation. In many indications the non-habit-forming substitutes produce the same therapeutic effect and avoid the danger not only of addiction but also of cocaine poisoning and idiosyncrasy.

With a year's experience behind us it should be possible to introduce some alleviations into the regulations, as for example the permission to use a 20 per cent solution and the hitherto forbidden cocaine ointment. This short period of time, however, has sufficed to show that the substitute preparations, particularly ethyl aminobenzoate, procaine hydrochloride, butamin and the newer Larocain and Pantocain (local anesthetics of the paraminobenzoyl series), can in many cases completely replace cocaine, even in the upper air passages, though none of them are entirely adequate for the eye.

As a result of the measures, the consumption of cocaine in Germany, which during the years 1925-1930 was about 400 to 450 Kg. a year, has fallen to less than half this amount in 1931. It is clearly fair to my German colleagues to state that, even before the introduction of these regulations, they had been so impressed by their experience of cocaine addiction in the post-war period that they themselves had restricted as far as possible the use of cocaine. The supply of good substitutes and the increasing attention which these have received has greatly helped in this effort to avoid cocaine and to prescribe it only when it is absolutely necessary. I know of practicing otorhinolaryngologists who have entirely desisted from the use of cocaine even in major operations and who never use it under any circumstances. Furthermore, they express their satisfaction at being thus relieved of the danger of cocaine poisoning.

The therapeutic limitations which these regulations as to the prescription of opiates and cocaine have imposed on the German medical profession are certainly very strict. The physicians, however, have readily submitted to these inroads into their freedom in the choice of remedies, in order to play their part in the struggle against drug addiction, and to contribute to a really effective campaign against this evil in the interests of the nation's health.

One can only ascribe to these measures the credit for the fact that in Berlin, which was formerly, for German standards, thickly sprinkled with illegal drug dealers, there has not been a single case of falsification of a cocaine prescription for over a year, no pharmacist is permitted to hand over cocaine substance, and the weak solutions that are employed for patients are of no value to the secret dealers. Further, there has undoubtedly been a decrease in the number of these illegal dealers and I know from my own experience that it is now difficult to obtain cocaine through these channels in the night resorts of Berlin. Illegal morphine trading is also infrequent, as was always the case. Here the addicts obtain their supplies through credulous practitioners and the falsification of prescriptions. The latter have increased of late and are skilfully carried out. Two-tenths gram of morphine is always a useful amount even for nonmedical purposes, and in this case the undissolved substance is of no special importance. The postwar days, when it was easier in Berlin to obtain 1 Kg. of morphine illegally than 1 cg., are definitely over. From the great and rapid strides recently made, I think it may be said on mature reflection and without undue optimism that the time is not far distant when a substitute will be found for cocaine which will satisfy the most exacting demands of specialists in any branch of medicine. The time will then have come to declare cocaine to be obsolete and to destroy the plantations. Commerce should then no longer triumph over science, and cocaine addiction will no longer form a world problem.

---

[12] Wolff (footnote 6, second reference).

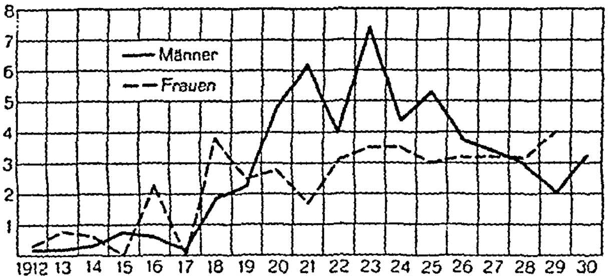

Fig. 11.—Morphine addiction at the Charité (Berlin): solid line, men; broken line, women.

Is it possible to entertain the same hope with regard to the opiates? Here I am somewhat skeptical. It is true that in this field also progress has been made in many directions, and I would like to give an example from Germany. The sharp rise in the consumption of habit-forming drugs and, for physicians, still more important, in the number of addicts which occurred after the war is well known. It is not surprising, however, that this abnormally inflated number of morphinists and cocaine addicts should again shrink with the restoration of normal conditions, as is shown in the accompanying curves. From these figures, taken from the Prussian medical statistics, it will be seen that there was a gradual increase up to 1923, when the climax of German inflation was reached (fig. 9). The same is shown in the curve obtained from the statistics of the Berlin University Psychiatric Clinic of the Charité for morphinism and cocaine addiction (figs. 11 and 12).[13] The much larger proportion of males affected is noticeable. There is no doubt that the increasing anxiety for the difficulties brought by every new day, the inflation, the uncertainty of the very necessities of life coming as a climax to the strain of the war and the tragedy of its ending, led many to seek a temporary relief in narcotics. That this was only a passing phase and that, in spite of the 'apparent abandon, the core of the nation remained sound, is shown by the rapid fall of the curves after the return of more stable conditions. Nevertheless the percentage of addicts still remains higher than it was in the prewar period. This is perhaps not surprising when it is remembered that there will always be morphine addicts so long as the physician is obliged to use this remedy which heaven has given us. The evidence that I have presented as to the rapid and at times astonishing decline in the consumption of opiates and cocaine, however, justifies the hope that the stringent regulations introduced into Germany will still further reduce the number of addicts simply because the patients and physicians are constantly confronted by increasingly difficult obstacles. Moreover, the economic position no doubt plays a part since it compels individuals to attempt to free themselves from the addiction on account of the great expenditure it entails and also because they know that it is harmful. If this is not so, the individual's family and more especially his physician must intervene. In the treatment of addicts it is essential not only that the physician be experienced and learned but also that he possess a strong personality. Important and interesting as it is, I cannot within the limits of this survey enter on a description of the details of treatment of addicts. I will only say that in Germany the bulk of opinion is in favor of the sudden withdrawal method[14] of Bonhoeffer and others as the remedy of choice, apart from a few contraindications, as I could bring evidence to show.[7] The most severe symptoms of abstinence may be tided over by the inducing of several days' sleep, and the newest method of treatment by means of insulin with or without grape sugar,[15] appears to be a scientifically justified and promising method which, however, requires further confirmation. Much work is still to be done, and the commission appointed by the health committee of the League of Nations "to study the treatment of drug addicts" should be able to collect valuable material from the scientific literature of all countries. The preliminary work is already making rapid strides.

## CONCLUSION

Thus I have once again returned to purely medical matters, which, in spite of necessary statistical material and important political considerations, is of most interest to us. The amount of opium produced at present is far in excess of what is required medically. This is known by every one. The practical difficulty lies in economic considerations, in the impossibility of obtaining accurate figures of the production in inner Asia, and finally in the question as to what the poppy cultivators can grow as a means of livelihood.

These difficulties have yet remained unsolved in spite of all the efforts of the League of Nations. The position as it exists in British India, for example, permits of a certain amount of hope. Morphine is needed and will continue to be needed so long as there is illness. A time will perhaps come, however, when in the search for a therapeutically active substance the ideal morphine will be discovered, the Eumorphin, which will possess all the properties of morphine including the euphoric effect but which will no longer lead to habituation and addiction.

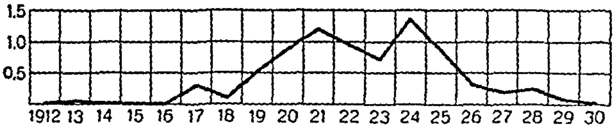

Fig. 12.—Cocaine addiction among men and women at the Charité (Berlin).

The results thus far attained in this field are encouraging, for there is reason to hope that the research work of the future will be crowned with success similar to that which has been witnessed with cocaine. That we are on the way to such a discovery I have shown by a few examples. The widespread interest in this problem is evidenced by the activities and research studies being undertaken in many countries. The coordinate program of the several agencies in the United States concerned with these matters must eventually contribute something to the sum total of knowledge on this subject. It may be that the chemical researches being carried out under the auspices of the National Research Council in the Cobb Laboratories of the University of Virginia, which have made so profound an impression on me, side by side with pharmacologic experiments and clinical trials, will lead to this achievement. Furthermore, side by side with this undertaking, which, like all research work, must be regarded for the moment as theoretical, comes another activity promising tangible and more immediate results: I refer to the program of the United States government for the control, segregation and treatment of those addicted to the use of habit-forming narcotic drugs.

We must continue to fight against addiction and the bodily and mental decay of the individual and of large sections of the population in many lands, and must increase our efforts whenever possible. Only when we have found this ideal morphine will the physician be given an all-powerful weapon. Then only will the end of the road be in sight and, by the cooperation of physicians, scientists and governments all over the world, drug addiction will cease to be a world wide problem.

# CHRONIC PEPTIC ULCER IN CHILDREN

LEON BLOCH, M.D.; I. P. BRONSTEIN, M.D.
AND
A. M. SERBY, M.D.
CHICAGO

A thorough study of available reports emphasizes the infrequency of chronic peptic ulcer in children. Up to twenty years ago it was considered a rarity, but within the last few years it has been encountered more often. Too often, however, this condition remains unrecognized clinically. Ulcers in childhood are overlooked because digestive upsets are not given the careful attention they merit. It is therefore of the utmost importance to bear this possibility in mind in order that the mortality associated with profuse hemorrhage, pyloric obstruction and perforation with peritonitis may be avoided. This study does not include cases of melena neonatorum, in some of which acute ulcers are found.

Sturtevant and Shapiro[1] found only five cases of gastric ulcer in children in 7,219 necropsies. From 1906 to 1925, in 8,260 (6,664 duodenal and 1,596 gastric) peptic ulcers at the Mayo Clinic, Proctor[2] discovered only two in children, one duodenal and one gastric ulcer. Proctor analyzed the literature and by his standards accepted only nineteen cases in children: sixteen in girls and three in boys; three duodenal and sixteen gastric. Six perforated and three bled profusely. Three improved with medical management and seven came to operation. Proctor reports three cases, in two of which gastro-enterostomy brought relief. Dickey[3] states that the diagnosis is usually made at operation or necropsy, and reports three cases diagnosed clinically. Loeber[4] describes the case of a girl who vomited material containing occult blood. Roentgen examination revealed a penetrating gastric niche high on the lesser curvature. The child improved on a modified Sippy regimen. Palmer[5] studied a series of patients in whom the correct diagnosis was made or suspected in only ten cases. He stresses the need for increased diagnostic acumen. He probably led the way in surgery, having performed a gastro-enterostomy in a six months infant with a duodenal ulcer. Holt and Howland[6] advocate symptomatic treatment because of the uncertainty of diagnosis and consider surgical intervention rarely justifiable. Allen A. Jones,[7] Thiele[8] and H. M. Richter[9] concur that gastric and duodenal ulcers are rare but not unusual. Miller and Gage[10] obtained by gastro-enterostomy permanent relief for at least twenty-one years in a 7 year old girl who had had a chronic cicatrizing duodenal ulcer since 6 months of age. Hurst and Stewart[11] at Leeds, in 200 cases of peptic ulcer, found none in the first decade and only eight in the second decade of life. Proctor of the Mayo clinic, quoted by Hurst and Stewart, states that 16 of their last 1,000 gastric ulcers and 26 of their last 1,000 duodenal ulcers gave histories of gastro-intestinal upsets dating back to childhood, in some cases to 4 or 5 years of age. Barford of New Lodge clinic, also quoted by Hurst and Stewart, found no cases in the first decade of life, but traces the history in many cases of peptic ulcer to that period. Paus's[12] statistics revealed only 2 cases in children, among a total of 168 cases, in whom operation was performed. De Toni[13] considers ulcers in children to be acute and secondary in type, running a rapid course and necessitating emergency surgery. He presents one case in a child of 10. Thiele[14] gives his experience with chronic peptic ulcer in a child of 2. Moynihan[15] agrees that the symptoms of chronic peptic ulcer often date back to the age of 10 or earlier. One of us (L. B.) in a study of 450 cases of peptic ulcer found 12 patients under the age of 20. In these the symptoms had begun three to five years before the first visit to a physician. One gave a history of distress beginning at 7. Many patients presented themselves for examination in the early thirties and late twenties, with a history of symptoms of fifteen years' duration, indicating that duodenal ulcer would not appear to be rare in the second decade of life. All these cases were confirmed by roentgen examination and the finding of a duodenal defect.

The following five cases came under our observation:

## PROTOCOLS

Case 1.—B. W., a girl, aged 9½ years, who was previously in perfect health, had stomach trouble for three years. The

symptoms came on gradually with no apparent predisposing factors but were accompanied by an urticarial rash. At first a definite seasonal variation occurred, the child feeling worse in spring and fall, but of late the distress had been continuous. The pain, cramping or nauseating in nature, usually appeared several hours after eating but sometimes immediately before and at other times immediately after eating. Belching, sour taste and bloating were occasionally noted. External heat always brought relief, food taking did occasionally and bowel movement never. Baking soda was never tried. No relation could be traced to the type of diet. Remissions appeared spontaneously. Since the urticarial rash appeared with the "stomach trouble," skin tests were performed. The allergy tests with pork, raisins, string beans, rice, potatoes and plums were positive. At present the child eats most of the aforementioned foods with impunity. During the past three years various medicines, quartz light and diet have failed to produce relief. The child has never had acute appendicitis, jaundice, tarry or clay colored stools, diarrhea or bloody vomitus.

Examination revealed tenderness in the epigastrium. An Ewald test meal showed free acidity 28 and total acidity 48. Stool examination revealed no occult blood. Roentgen examination revealed a defect on the posterior wall of the duodenum (on four examinations) and spasticity in the colon in twenty-four hour examinations with a barium enema. Both primary and dye gallbladder plates were normal. This patient was put on a mashed, puréed diet without meat and given a mixture of tincture of belladonna and camphorated tincture of opium in April, 1931. No alkalis were advised. Relief appeared at once.

Case 2.—M. Z., a girl, aged 11 years, had been well up to six months before the time of examination, when she began to suffer with epigastric cramps and the passage of bright red blood with stools. The pains occurred at least once daily and bore no relation to food taking, type of diet or bowel movement. The pain appeared at any time of the day but not very often at night.

The patient was well developed and well nourished. Tenderness was noted in the epigastrium, right lower quadrant and left lower quadrant. Proctoscopic and rectal examinations gave normal results. An Ewald test meal aspiration contained 15 free acidity and 57 total acidity and no occult blood. Stools contained 4 plus occult blood and no ova or parasites. Roentgen examination disclosed a defect on the posterior wall of the duodenum on several examinations, a tender segmented appendix, and spasticity and tenderness of the colon. Meckel's diverticulum could not be demonstrated, and the gallbladder was normal by both primary and dye plates. This patient improved under a modified Sippy management with bed rest for three weeks.

Case 3.—N. S., a boy, aged 13 years, had been well up to five months before examination, when sharp epigastric pains began to appear quite regularly, four or five times daily, half an hour after meals and occasionally before breakfast. The pain lasted about fifteen minutes. No nausea occurred. There was no relationship to bowel movement. A low residue diet had not relieved the distress. The patient's uncle had had an ulcer.

The patient was thin and well developed; he weighed 93 pounds (42 Kg.). Marked deep tenderness was noted at the umbilicus and slight tenderness along the left lower quadrant. The Ewald test meal examination showed free acidity of 32 and total acidity of 52. Stool examination revealed positive occult blood. Roentgen examination disclosed a defective duodenal bulb on two examinations. Examination of the appendix, colon and gallbladder (primary and dye films) gave negative results. On a modified Sippy management the patient's distress disappeared except for a transitory pain two or three times weekly.

Case 4.—F. A., a girl, aged 5 years and 1 month, who was seen by one of us (L. B.) in consultation with Dr. W. J. Corcoran, had had no gastro-intestinal disorder up to one month before. Constipation had been noted for four months and abdominal pain immediately after eating for one month. Elimination of raw fruits and vegetables for one month had not improved the condition. There was no vomiting or jaundice.

Physical examination demonstrated nothing abnormal. The stools contained no occult blood. Roentgen examination revealed a duodenal defect. The patient and films were seen by one of us (L. B.) at the Mercy Hospital in Chicago. The child was put to bed and treated by a modified Sippy regimen. In one week the pain had disappeared, and although the patient is on a full diet it has not reappeared during the past two years except for one slight attack of one month's duration.

Case 5.—G. K., a girl, aged 8½ years, was referred to one of us (L. B.) by Dr. H. M. Richter. Until the age of 3 months she vomited almost everything she ate. At the age of 10 weeks she vomited some dark blood. The vomiting then lessened gradually until she reached the age of 6, after which she vomited rarely. At about this time she again vomited some dark blood. One year before she was seen by Dr. Richter she began to complain of occasional substernal heaviness coming on two hours after eating, which was relieved by taking food or soda. One month later the heaviness became a pain and occurred daily and after every meal. Taking food relieved the pain. One month before we saw her she vomited some dark blood and passed tarry stools. The patient was a well developed stout child in whom nothing abnormal was found aside from a marked pallor. Two roentgen examinations by different observers disclosed no duodenal defect. Nov. 19, 1931, the hemoglobin was 50 per cent (Dare) and red blood corpuscles numbered 3,120,000. This remained the same until the end of January, 1932, when the mother reported that the child had passed several tarry stools. The hemoglobin at this time was 35 per cent and the red blood corpuscles numbered 2,810,000. As the child had been in bed continuously for several weeks without improvement and the loss of blood continued, she was referred back to Dr. Richter. A transfusion of 300 cc. of blood was given, February 4. The next day an operation was performed by Dr. Richter and disclosed two small superficial ulcers located on the posterior wall of the duodenum about 1 cm. from the pylorus. It was necessary to incise the duodenum to find them because there were no external evidences of the ulcers on the peritoneal surface. The ulcers were cauterized and a pyloroplasty was done. The first bowel movement after the operation showed considerable blood, the following two showed a very small amount, and the subsequent one showed none.

## COMMENT

Chronic peptic ulcer in children does not produce the classic symptomatology noted in adults. Continued abdominal distress or cramps several times a day may constitute the sole subjective evidence. The hunger pain of ulcer is rarely noted. The relation to alkalis has not been worked out in children and is not important, as stated by Bloch and Serby.[16]

On examination, just as in adults, a tender point may be found in the epigastrium. The Ewald and stool examinations may not assist in making the diagnosis. Roentgen examination reveals a definite duodenal defect. The defect should be verified by subsequent examinations to rule out spasm of extrinsic origin. Four patients showed duodenal defects, although others on investigation have found more gastric than duodenal lesions. This condition must not be confused with one occurring in children in whom pain and vomiting come on a short time after meals and in whom roentgen examination shows a dilated duodenum and a slowing of the passage of duodenal contents at the duodenojejunal junction as a result of a narrowing produced by pressure of the root of the mesentery on the duodenum. The therapeutic results in these patients have proved satisfactory in four and poor in one on medical management, a modified Sippy regimen. This consisted of rest in bed for three weeks, milk and cream, 2 ounces every two hours. Three patients received calcium carbonate, 10 grains (0.65 Gm.) every hour and magnesium oxide only when constipation ensued. Tincture of belladonna, 5 minims (0.3 cc.) twice a day was administered. The diet was augmented by purées, soft-boiled eggs, cereal and custard. Later, a six meal schedule was instituted and alkalis were decreased to three times daily.

---

[16] Bloch, Leon; and Serby, A. M.: Use of Alkalis in the Treatment of Peptic Ulcer, J. A. M. A. **92**: 134 (Jan. 12) 1929.

The importance of allergy as a cause of gastro-intestinal pain must not be overlooked, as stated by Rowe, Duke and others. We wish to call attention again to case 1, in which evidence of allergy accompanied the onset of symptoms. It is to be noted that the patient is now eating some of the articles to extracts of which positive tests were obtained, without being affected. It is possible that an allergic response was instrumental in producing a duodenal ulcer and that other factors such as mechanical or chemical have produced chronicity in this case.

# CORONARY ARTERY DISEASE IN THE WORKING CLASSES

ERNST P. BOAS, M.D.
NEW YORK
AND
SAMUEL DONNER, M.D.
HARTFORD, CONN.

There is much evidence suggesting that angina pectoris associated with atherosclerosis of the coronary arteries, as well as thrombosis of the coronary arteries, is becoming more frequent. Many famous clinicians of the nineteenth century remarked on the rarity of angina pectoris. In Germany, Bamberger[1] wrote that it was one of the rarest symptoms of heart disease. He had seen only six cases when he published his book in 1857. In the year 1845, of 5,171 deaths in Hamburg, only 3 were attributed to angina pectoris.[2] In Great Britain this syndrome seems to have been more common, for such men as Latham and Stokes write as though they had seen many cases; yet as recently as 1896 the distinguished Edinburgh consultant Balfour[3] wrote that he had seen ninety-eight cases of angina pectoris in ten years. In the United States, Flint[4] found angina pectoris a rare disease. He encountered only 15 cases in 338 consecutive cases of heart disease. Osler,[5] in 1897, had seen only forty cases of true angina pectoris. Today every internist sees these patients in far greater numbers. We have seen 225 new cases of angina pectoris or coronary thrombosis in less than two years. This discrepancy can be explained only in part by greater precision in diagnosis. Undoubtedly the increasing custom of special cardiologic examinations, and especially the recognition of the value of electrocardiographic examinations in the diagnosis of coronary disease, brings many more of these patients to the office of the specialist than in former generations.

Many authors are of the opinion that the great stress and hurry of modern life has brought about a greater frequency of disease of the coronary arteries. In support of this assumption they point out that it is encountered especially among the well-to-do and among men of big affairs and great responsibilities; it is assumed that the strain of modern business and professional life in some subtle way leads to early degenerative changes in the coronary arteries. Phillips[6] speaks of angina pectoris "occurring in people who work with their brains at high pressure"; it has often been referred to as the doctor's disease. Osler, Huchard,[7] Allbutt, Gallavardin,[8] Danielopolu and Brooks[9] all support this view. It is true that Allbutt expresses some doubt as to the validity of the published statistics and that Huchard and Gallavardin add that they have seen many cases in workmen. Gibson[10] seems to be alone in emphasizing that in districts where hard mechanical occupation is the rule, angina pectoris is far from uncommon among the working people.

During the past two years one of us, as cardiovascular consultant to a large organization composed almost exclusively of industrial workers, has had the opportunity of studying more than 600 patients of this social group who were referred by their family physicians because of symptoms that suggested heart disease. The clinical material included the male wage earners, their wives, who for the most part took care of their homes, as well as their children. The patients were all Jews, and the largest number of the wage earners were employed in the garment industry in New York City. The present study comprises 615 consecutive cases of this group. Although in this paper we wish to direct attention particularly to those patients suffering from disease of the coronary arteries, a few general statistics will serve as a background. These are presented in table 1.

Table 1.—*Etiologic Classification of Patients with Cardiac Disease*

| Condition | Males | | Females | | Total | |
|---|---|---|---|---|---|---|
| | Number | Per Cent | Number | Per Cent | Number | Per Cent |
| Coronary artery disease* | 144 | 45.5 | 27 | 13.7 | 171 | 33.4 |

| Miscellaneous cardiac conditions | 16 | 5.0 | 9 | 4.5 | 25 | 4.9 |
| Totals | 316 | | 196 | | 512 | |

* Patients with coronary artery disease and hypertension are listed only under the heading coronary artery disease. There were forty-nine males and twenty-two females, or a total of seventy-one patients with both conditions.

Of the 615 persons, 233, or 38 per cent, were women; 97 were children under the age of 16. The age and sex distribution is given in detail in table 2. One hundred and three, or 17 per cent of the whole series, were found to have no cardiovascular disease, no functional murmurs and no neurocirculatory asthenia. This leaves 512 cases in which a cardiovascular diagnosis was made: 171, or 27.8 per cent, of the whole series; and if the 103 cases without cardiovascular disease are subtracted, fully one third of the remainder had evidence of disease of the coronary arteries. This is an exceptionally high incidence.

We employed strict criteria for the diagnosis of coronary artery disease. The diagnosis of angina pectoris was made only if the history revealed a typical Heberden's syndrome, i. e., substernal pressure or pain provoked by effort, compelling the patient to halt his activities. In many instances there was typical radiation to the left arm. Coronary sclerosis with myocardial degeneration was diagnosed when, in addition to the classic history, there were electrocardiographic changes, which are generally accepted as indicative of myocardial injury, such as deformation of the RT segment, or the T wave, or marked alteration of the QRS complex. Coronary thrombosis was diagnosed when the history revealed a severe attack of substernal pain, lasting two or more hours, accompanied by symptoms of shock, usually with subsequent cardiac insufficiency compelling bed rest for a period of weeks following the attack. Most of these patients also exhibited electrocardiograms accepted as characteristic of myocardial injury. Those who did not had such typical histories and physical manifestations that there could be no doubt as to the nature of their attacks. We tried to include only cases in which the symptoms were attributable to disease of the coronary arteries, and excluded all cases of syphilitic aortitis, as well as all with aortic insufficiency of whatever origin.

Few statistics of the incidence of various types of heart disease are given in sufficient detail to make them available for comparison. We have checked table 2 on page 302 of White's [11] book and have been unable to convince ourselves that the diagnostic criteria of the various authors who have been drawn on are sufficiently uniform to warrant a direct comparison of their experiences, certainly not in the categorical manner in which they are made to appear. The data of White and Jones,[12] however, are specific enough to allow of a direct comparison. Their material, too, was drawn from a region in which rheumatic fever occurs with about the same frequency as in New York City. Table 3 presents a compilation of their experience with disease of the coronary arteries, and of ours.

In a series of 300 cases, Wood [13] found angina pectoris in 10 per cent of the white and in 5 per cent of the Negro race. In about the same number of cases observed in a chest clinic in Iowa, 7 per cent had angina pectoris, and 0.7 per cent coronary thrombosis.[14] Schwab and Schulze,[15] among 1,660 patients with organic heart disease seen in the outpatient department of a hospital in Texas, found 20 per cent with arteriosclerotic heart disease. The majority of these apparently had symptoms or signs of coronary artery disease. Thus, in a consultation practice among industrial workers we encountered twice as many cases of disease of the coronary arteries as did White and Jones, whose figures seem to be representative of the general experience. This is all the more remarkable in view of the age distribution of our patients, for in our series there is a predominance of the younger age groups. Eighty-four per cent of our whole series, as contrasted with 52 per cent of White's patients, were under the age of 50. Nor did we have an undue preponderance of males; 62 per cent of our series and 56 per cent of White's were males. In table 4 the incidence of angina pectoris in White's consultation series and in ours is tabulated according to age groups. Even at the same ages there is a much higher frequency of angina pectoris in our series.

The conclusion seems inescapable that in our clinical material, composed of Jewish industrial workers and their wives, disease of the coronary arteries is much more frequent than in other comparable published series. It seems that coronary sclerosis, far from finding the majority of its victims among individuals of wealth and learning, cripples with especial frequency at least certain groups of workmen.

Indeed, certain evidence suggests that the disease is more malignant among these workmen. This implication lies chiefly in the age distribution of our cases, compared to that of other published series. In table 5 the age distribution of 2,454 published cases is recorded. Whereas 71 per cent of our patients with coronary artery disease were under 51 years of age at the time of onset of their symptoms, the combined experience of all the other observers gives only 33 per cent of cases under the age of 51. Only Huchard [7] and Kahn and Barsky,[16] whose figures are respectively 50 and 60 per cent, approach our figures. It is most interesting to note that, at the time their paper was written, Kahn and Barsky were seeing the identical class of patients who form the subject of our analysis and that their figures most closely approximate ours. Conner and Holt [17] found that one third of their patients

with coronary thrombosis had experienced their first attack before the fifty-first year of life, and they concluded that coronary thrombosis must be regarded as a disease of early middle life.

The organization from which our patients were drawn, and which has approximately 70,000 members, is composed largely of men in the third to fifth decades of life. Eighty-eight per cent of the members are between 20 and 50 years of age. This explains why so few of our patients are in the older age groups and why the percentage incidence of the cases under the age of 50 is so high. Yet, as is shown in table 4, in which White's cases and ours are arranged according to age groups, angina pectoris is much more frequent in our series at all ages. The very fact that the population from which our material is drawn is preponderantly young makes it all the more remarkable that one third of all the cardiac patients were suffering from disease of the coronary arteries.

Table 3.—*Percentage Frequency of Coronary Artery Disease Among Cases of Heart Disease*

| | Percentage Frequency Among All Cases of Heart Disease | | | |
|---|---|---|---|---|
| | White and Jones | | | Boas and Donner |
| | Consultation Practice 1,000 Cases | General Practice 1,000 Cases | Hospital and Dispensary 1,000 Cases | Consultation Practice, Workmen, 512 Cases |
| Angina pectoris......... | 4.2 | 2.8 | 0.7 | 11.9 |
| Angina pectoris and myocardial degeneration... | 7.7 | 10.0 | 5.9 | 10 3 |
| Coronary thrombosis.... | 4.2 | 2.3 | 0.6 | 11.1 |
| Total coronary disease | 16.1 | 15.1 | 7.2 | 33.3 |

It may be suggested that the marked discrepancy between our experience and that of others may be due primarily to different diagnostic criteria; that possibly we are too facile with the diagnosis coronary artery disease. That this does not obtain is shown by a study of the fifty-four cases of coronary artery disease seen by one of us in private consultation practice during the same period in which the workmen were observed. Here the age distribution corresponds to that of other observers; only 35 per cent were under the age of 51.

We can discover no unusual factors predisposing to disease of the coronary arteries in our patients. Hypertension was present in seventy-one, or 41.5 per cent of the cases. A systolic blood pressure of 150 or over was regarded as evidence of hypertension. This corresponds to the incidence of hypertension reported by Levine.[18] Two thirds of the patients with hypertension and coronary artery disease were under the age of 51—corresponding to the age distribution of the whole series. Thus an exceptionally high incidence of hypertension cannot be regarded as the cause of the frequency of coronary artery disease in the younger age groups.

In spite of the relative frequency of diabetes among Jews, only eight, or 4.7 per cent, of our series had diabetes. This contrasts with an incidence of 7 per cent found by Levine.[19] Thus the early development of coronary artery disease in these workmen cannot be attributed to an excessive frequency of diabetes. The experience of others has been that, as a complication of diabetes, angina pectoris or coronary thrombosis appears on the average at the age of 60.[20] The comparative youth of our patients probably explains the low incidence of diabetes.

We have divided our patients with coronary artery disease into three groups: those with angina pectoris, those with coronary artery sclerosis and myocardial degeneration, and those with coronary thrombosis. The criteria for these diagnoses have been indicated at the beginning of this paper. From table 2 it appears that the patients were fairly evenly divided among these three categories. There were sixty-one with angina pectoris, fifty-three with coronary sclerosis and myocardial degeneration and fifty-seven with coronary thrombosis. Thus, in about two thirds of the cases there was definite evidence of myocardial damage when first examined. The younger age groups, under 51 years, were represented in the same high proportion in those patients with coronary artery sclerosis and thrombosis as in those with symptoms of angina pectoris, but with no physical or electrocardiographic signs of myocardial disease. Since myocardial degeneration and coronary thrombosis is diagnosed on objective evidence, the high incidence of coronary disease cannot be explained by an increased nervous sensitivity of these patients, which might lead them to consult a physician on slight provocation.

Hypertension occurred in about one half of the patients with simple angina pectoris and with myocardial degeneration, and in one fourth of those with coronary thrombosis. In view of the frequent permanent drop in blood pressure following coronary thrombosis, this is readily explained. It is fairly safe to assume that most patients who have experienced coronary thrombosis and who have a low blood pressure but a large heart had hypertension before the attack. If these are added to the hypertension column, hypertension will be found as frequently among the group with coronary thrombosis as among the others.

Moderate or considerable cardiac enlargement was observed in more than one half of all the cases.

Twenty-six, or 15 per cent, of the 171 patients with disease of the coronary arteries were women, and 22 of these women had hypertension, often of considerable degree, whereas only one third of the men had hypertension. Sixteen of the twenty-six women were under the age of 51, corresponding to the age distribution of the men. Sixteen women had only symptoms of angina pectoris, eight had coronary sclerosis with myocardial degeneration, and only two had coronary thrombosis.

Table 4.—*Incidence of Angina Pectoris by Age Groups*

| | White and Jones Consultation Series | | | Boas and Donner | | |
|---|---|---|---|---|---|---|
| | Number of Cases | | Percentage Frequency of Angina Pectoris | Number of Cases | | Percentage Frequency of Angina Pectoris |
| Ages | Total | Angina Pectoris | | Total | Angina Pectoris | |
| 0-10 | 25 | 0 | .... | 31 | 0 | .... |
| 11-20 | 55 | 0 | .... | 67 | 0 | .... |
| 21-30 | 110 | 1 | 0.9 | 25 | 0 | .... |
| 31-40 | 141 | 0 | .... | 118 | 14 | 11.8 |
| 41-50 | 190 | 8 | 4.2 | 188 | 23 | 14.0 |
| 51-60 | 204 | 21 | 10.2 | 65 | 15 | 23.0 |
| 61-70 | 208 | 11 | 5.3 | 17 | 4 | 23.5 |
| Over 70 | 67 | 1 | 1.5 | 1 | 0 | .... |

The reason for the high incidence of disease of the coronary arteries in our series which comprised largely individuals under the age of 50, is not apparent.

We have shown that it is not determined by an undue frequency of hypertension or diabetes mellitus. Nor does obesity play a rôle. All the patients were Jews, and it is possible that there is a racial predisposition. Both Edens[21] and White[22] have remarked that Jews seem especially prone to this disorder, although they offer no data to fortify their statements. White believes that disease of the coronary arteries is also more common in Italians. In this connection it is interesting to recall the supposed rarity of angina pectoris among Negroes, and the finding of Schwab and Schulze that arteriosclerotic heart disease occurs less frequently among Negroes.

* J. Forbes (Cyclopedia of Practical Medicine, London, 1833) just divides his patients into two groups, those below 50 and those above 50.

† The age of these thirty-six patients is not mentioned, except that they were not under 50.

The frequency of angina pectoris among Jews and Italians, and its rarity among Negroes, has usually been explained by their differing "nervous constitution." The high strung, sensitive individual is supposed to develop symptoms of angina pectoris more readily than one who is phlegmatic and care free.

Czyhlarz[23] in this way explained his observation that at the Allgemeine Krankenhaus in Vienna, where the patients for the most part are of the "neurasthenic middle classes," there is much angina pectoris, while at the Franz Josef Hospital in the same city, where the patients are chiefly manual workers, the disease is rare. A hypersensitive nervous system may send a greater proportion of patients to consult a physician, but it does not account for the development of the underlying atherosclerosis of the coronary arteries, nor does it explain the many coronary thromboses, coming without previous warning and first drawing attention to the cardiac incapacity. It will be recalled that one third of our patients had coronary thrombosis, and another third evidences of myocardial degeneration. We are inclined to the belief that the nervous system plays a secondary rôle in the genesis of the syndromes of coronary artery disease, and that some unknown factors are more fundamental. Whether heredity, occupation or diet are important in this connection remains a matter for speculation.

We have gained the impression that, roughly speaking, there are two types of disease of the coronary arteries. The one occurs as a phase of a general arteriosclerosis; it is part of the process of senescence. It is encountered in the elderly, in men over the age of 60, who have hardened and tortuous peripheral arteries, dilated sclerotic aortas, and often a well marked arcus senilis. In these patients the interference with the blood supply of the heart is but an incident of the general arterial disease. The second type occurs in young vigorous men between the ages of 35 and 50 who give few other indications of arterial disease but who may have an essential hypertension. In them the cardiac signs and symptoms stand out as the only evidences of body deterioration. In them, too, it seems as though the progress of the disease was more malignant.

## SUMMARY

An analysis was made of 615 males and females of the industrial class in New York City who were referred with the presumptive diagnosis of heart disease. Eighty-eight per cent of the population from which these patients were drawn were under the age of 50. Almost one third of the 615 referred patients had disease of the coronary arteries. Of those with disease of the coronary arteries, 71 per cent were under the age of 51. This represents an exceptionally high frequency of coronary artery disease, which is all the more remarkable in view of the preponderance of individuals under the age of 50. Our data demonstrate that coronary artery disease, contrary to general belief, is more common, and occurs earlier in life, at least in certain groups of industrial workers. They suggest the desirability of further studies along similar lines with different racial and occupational groups.

# HOOKWORM DISEASE IN WHITE SCHOOL CHILDREN

## COMPARISON OF TWO METHODS OF SURVEY

CH. WARDELL STILES, Ph.D.
WINTER PARK, FLA.

It is rather generally acknowledged that a microscopic examination should precede treatment in all cases of hookworm disease. This view is based on sound experience and sound theory. The microscopic examination is especially important if carbon tetrachloride is to be used in treatment, for if the case is complicated with Ascaris infection, the clinician should know this fact before treatment is instituted.

Opinion is perhaps not nearly so unanimous as to whether one is justified in drawing conclusions regarding the status of hookworm disease on the basis of symptoms observed in a brief inspection of school children unless the diagnosis is made and confirmed in the individual cases by microscopic examination. My position in this matter is that any person experienced in the clinical side of this infection is thoroughly justified by a brief inspection (sometimes referred to as "street car diagnosis") of white children in arriving at conclusions as to whether hookworm disease is playing any material rôle among the children and that for purposes of general estimate the only additional support necessary for a survey of this kind is an occasional check up with the microscope by the person making the inspection or a record of definite microscopic examinations showing that hookworm disease has been demonstrated in the school or in the immediate locality in question. In severe and marked cases it is difficult for an experienced inspector or clinician to go astray in his conclusions in this disease among white children; his mistakes occur in the very light cases or in cases of other conditions, (such as Ascaris infection, and malnutrition) simulating hookworm disease. I am, of course, aware that some of my colleagues, especially laboratory workers, are not in full accord with me in this view.

Through the cooperation of Dr. Floyd Johnson, county health officer, and Prof. C. C. Russ, county superintendent of education, of Columbus County, North Carolina, I am able to present some comparative data obtained by the two methods in question. I have recently surveyed the children of five rural white schools in Columbus County by the symptomatic method, without stopping to make microscopic examinations. All these five schools, however, were definitely known to me in former years to have had hookworm cases among the pupils.

Specimens for microscopic examination were forwarded by Dr. Floyd Johnson from two of the schools and from one additional school not included in the symptomatic survey. The comparative results obtained by the two methods are shown in table 1.

Table 1.—*Comparative Results Obtained by Two Methods*

* Includes all gradations from very severe cases, such as dirt eaters, to doubtful suspects.
† Includes all hookworm infections from severe infestations to exceedingly light infections, such as carriers.
‡ Deduction of 20 per cent for average theoretical error.
§ Seven of these were of preschool age and were not seen in the original clinical survey.

As a few of the children may be absent from one of the examinations but present in the other, the figures in table 1 are, of course, a comparison of the index of the children in general and not a mathematically exact analysis of 100 per cent identical children. The data here presented are not only a comparison between the two methods of estimates (one taking from less than an hour to at most two hours for each school; the other requiring many hours of work in collecting and examining the specimens); but the data represent also microscopic confirmation of the assertion in another paper that the "widespread impression that hookworm disease in man has almost disappeared from the United States . . . is not confirmed by theoretical considerations, by laboratory examinations or by clinical observations."

In the clinical survey, a portion of a school (number 28) in another state was inspected. Among sixty-one pupils seen, fifty children, or 82 per cent (corrected estimate 66 per cent), were selected as having hookworm disease and as suspects.

Thirty-three specimens were obtained from this school for microscopic examination and, of these, sixteen, or 48.5 per cent, were positive for hookworm. There is no way of knowing how many of these thirty-three children were among the sixty-one pupils seen in the symptomatic survey, nor is this matter of any particular importance. The important point is that for this school also the "widespread impression that hookworm disease in man has almost disappeared from the United States . . . is not confirmed by theoretical considerations, by laboratory examinations or by clinical observations." It is interesting to note that a prominent resident in this town said that hookworm was formerly very prevalent in his locality but that it had been eradicated.

As stated in another paper of this series, persons working by the quick method should hold in mind the theoretical error, which varies according to conditions of light, and so on; they are justified in estimating the approximate prevalence of hookworm disease of a school on this basis, but, as already emphasized several times, they are not justified, in my opinion, in instituting mass treatment, at least in this country, where a microscopic examination can be obtained free of cost to the patient.

In comparing the figures obtained in schools 14 and 15a (77 and 79 per cent) based on the symptomatic method with those (97 and 90 per cent) based on the microscopic method, it is seen that the former are distinctly conservative; for all practical purposes, in judging whether this infection is of educational and administrative importance to the school, the conclusion reached is as sound and valuable (perhaps more so) as (than) the conclusion based on the microscopic observations, for the latter considers only the worms, while the former considers the effect of the worms on the children.

Table 2.—*Microscopic Examination of Four Schools (Numbers 14, 15a, 15b, 28)*

| | |
|---|---|
| Total number of schools (in two counties, two states) in question.. | 4 |
| Total number of children examined microscopically............... | 199 |
| Positive for hookworms only .................................. | 104 |
| Positive for hookworms and Ascaris only........................ | 44 |
| Positive for hookworms, Ascaris and Enterobius only............. | 3 |
| Positive for hookworms and Enterobius only...................... | 5 |
| Positive for hookworms and Trichuris only....................... | 1 |
| Positive for hookworms and undetermined nematode egg............ | 1 |
| Total *positive for hookworms*................................. | 158 |
| Positive for Ascaris only...................................... | 6 |
| Total positive for Ascaris..................................... | 53 |
| Positive for Enterobius only................................... | 3 |
| Total positive for Enterobius ................................. | 11 |
| Total positive for Trichuris .................................. | 1 |
| Total positive for an undetermined nematode egg................. | 1 |
| Total number of children infected by one or more species of worm... | 167 |
| Total percentage of children infected by one or more species of worm | 84 |

The worm statistics cited for the seven schools have been confined entirely to hookworm infection. Taking other intestinal worms into account also, I obtained the data on the basis of microscopic examination in table 2.

# SPECIFIC IMMUNOTRANSFUSION IN THE TREATMENT OF SEPTICEMIA

## REPORT OF A CASE

WILLIAM BRODY, M.D.
AND
WALTER J. CROCKER, V.M.D.
PHILADELPHIA

The treatment of septicemia is frequently attended with great difficulties. Physicians often clamor for something specific and fall victims to many of the newer chemicals alleged to be of value in combating infections of the blood stream. In 1919, Sir Almroth Wright[1] pointed out several important principles in the treatment of septicemia: First, that adequate surgical drainage of infected foci is extremely important. Second, that it is possible to produce nonspecific bactericidal agents by inoculating blood in vivo or in vitro with different types of killed organisms; that such blood, from six to eight hours after the vaccination, has definite curative effects in many types of infections of the blood stream. Third, that specific immunization is of even greater value than the nonspecific procedures noted. Fourth, that ordinary blood transfusions may actually do harm in infections of the blood stream. He reported a case of septicemia treated with nonspecific immunotransfusion, with recovery.

In 1923, Colebrook and Storer[2] described their technic of nonspecific immunotransfusion. Comparatively little practical use has been made of their observations. More clinical application of nonspecific immunotransfusions should be made, because of their simplicity and possible good effect.

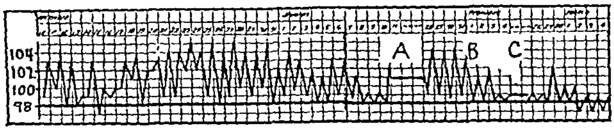

Chart 1.—Rectal temperature, with two gaps indicated by horizontal broken lines, through which periods there was little significant change: *A*, no significant change in remittent fever during this period; *B*, specific immunotransfusion; *C*, normal during this period.

Specific immunotransfusions require the aid of a competent bacteriologic laboratory. It is time consuming, but if one is fortunate in keeping the patient alive for four or five weeks and if the infection does not progress to a pyemic state, specific immunotransfusion may be a life-saving measure. Linser,[3] in 1925, and Hébert,[4] in 1928, reported favorable results with specific immunotransfusions in septicemia.

Our object in this paper is to report a case of septicemia due to Streptococcus hemolyticus occurring in a child, aged 9 years, who was treated by the usual methods without improvement. Treatment with blood from a specifically immunized donor produced remarkable improvement and led to the ultimate recovery of the patient. The treatment and laboratory studies will be reported in some detail.

## REPORT OF CASE

*History.*—E. P., an Italian boy, aged 9 years, admitted to the Children's Ward of the Philadelphia General Hospital, had been perfectly well until Dec. 3, 1930, when he first complained of headache. This was accompanied by some elevation in temperature. In spite of treatment by his family physician, his condition grew worse. A painful swelling appeared in the left temporal region. He became delirious at night and intermittent fever persisted. The patient was hospitalized. The past medical history was negative except for a tonsillectomy in 1929. The family history was irrelevant.

*Examination.*—The boy was markedly undernourished, quite ill, and in a semistuporous condition. The skin and mucous membranes were dry. Examination of the head revealed a tense, tender, painful, nonfluctuant swelling measuring 7 by 5 by 1 cm. in the left temporal region. The ears, eyes and nose were normal. There was no tenderness over any of the paranasal sinuses. The mouth presented sordes at the left angle and a dry, red tongue. The teeth were in excellent condition. The pharynx was slightly injected. The tonsils were missing. The neck was normal except for palpable nodes at the angles of both jaws. The chest wall was emaciated; the lung fields showed nothing of note. The heart was not enlarged; the rate was rapid and the rhythm regular. No murmurs were heard. The blood pressure was 108 systolic and 86 diastolic. The liver and spleen were not palpable. Some hyperperistalsis was noted. The genitalia and extremities were normal. No abnormal reflexes were elicited.

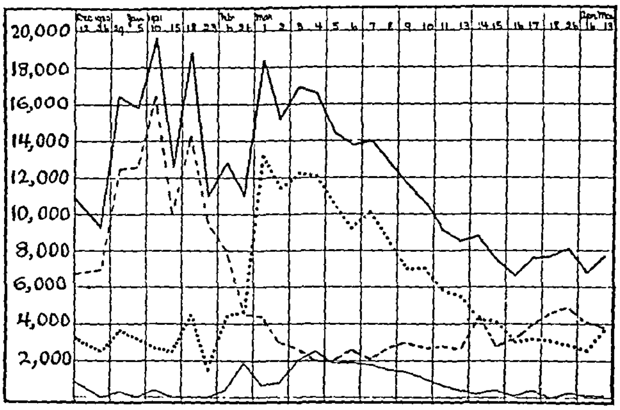

Chart 2.—Total and differential leukocyte counts expressed in absolute numbers throughout the hospitalization period: heavy solid line, total number of leukocytes; broken line, polymorphonuclears; dotted line, lymphocytes; light solid line, monocytes. Immunotransfusion, February 1.

*Laboratory Studies.*—Roentgenographic studies of the chest and teeth were negative. The ethmoid cells and left antrum showed some haziness and were considered suspicious foci of infection. The blood showed a neutrophilic leukocytosis. The Widal reaction was negative. A blood culture was positive for Streptococcus hemolyticus. No ova or parasites were present in the stools. The spinal fluid was normal.

TABLE 1.—*Blood Cultures*

| Date | Culture | Organisms |
|---|---|---|
| Dec. 13, 1930 | Positive | |
| Dec. 18, 1930 | Positive | |
| Dec. 21, 1930 | Positive | |
| Jan. 8, 1931 | Positive | |
| Jan. 15, 1931 | Positive | |
| Jan. 24, 1931 | Positive | |
| Feb. 1, 1931 | Transfusion of immunized blood, [illegible] cc. | |
| Feb. 6, 1931 | No growth | |
| Feb. 19, 1931 | No growth | |
| Feb. 26, 1931 | No growth | |

*Clinical Course.*—Blood cultures were repeatedly positive for Streptococcus hemolyticus (table 1). The child had chills and fever almost daily (chart 1) and a varying polymorphonuclear leukocytosis. He lost much weight and his general condition grew steadily worse in spite of surgical, chemical, serologic and ordinary blood transfusion therapy. (A complete summary of

treatment is given in table 2.) Anticipating that the therapeutic measures outlined in table 2 might not be curative, we started early to prepare a specifically immunized donor. We selected a donor who had previously been used with no beneficial effects for a transfusion of the patient. This donor was immunized with a vaccine prepared from the bacteria isolated from the patient's blood stream (table 3).

At weekly intervals for four weeks the donor received subcutaneously increasing numbers of killed organisms, beginning with 50 million and reaching 250 million. One week following the last injection the donor was bled of 150 cc. of blood and a transfusion of the patient was performed by the citrate method. No reaction followed the transfusion. Forty-eight hours after this transfusion his temperature came down to the normal level for the first time. Blood cultures thereafter were negative (table 1).

Agglutination studies with the causative organisms were done with the donor's and the recipient's blood serum, serum from convalescent erysipelas patients and serum used in the treatment of scarlet fever (table 4).

Three weeks following the immunotransfusion, the patient developed marked, right-sided, anterior, cervical adenopathy, coryza, a slightly injected throat and fever. The blood revealed a white cell count of 11,000; neutrophils were 41 per cent and lymphocytes 59 per cent, the latter being mostly of the young large forms.

Four days later the white count rose to 18,200, with 22 per cent neutrophils and 88 per cent young large lymphocytes. Daily blood studies were made of this phase (chart 2). The blood continued to show a marked absolute lymphocytosis; gradually the white cell count fell to normal and in about two weeks the differential approached normal. An increasing agglutination titer was observed during the latter phase of the disease (table 4).

## COMMENT

A case of Streptococcus hemolyticus septicemia was cured by transfusion from a specifically immunized donor, after five 150 cc. and one 50 cc. nonmodified blood transfusions had failed. In addition to the latter, surgical drainage of suspicious foci, Pregl's solution of iodine, intravenous injections of metaphen, polyvalent antistreptococcus serum and autohemotherapy were used without avail.

The blood picture from the beginning of the illness until three weeks following the immunotransfusion was one of a neutrophilic leukocytosis. A definite lymphocytic leukocytosis then occurred. At first large young lymphocytes appeared that were difficult to differentiate from monocytes, but, as time went on, these cells matured and were more easily identified. This reaction was accompanied by fever, adenopathy and a rising serum agglutination titer. The blood picture gradually returned to normal.

Nonspecific immunotransfusion should be performed primarily in septicemia. Specific immunotransfusion should be made possible by early isolation of the causative organism, preparation of a vaccine and active immunization of a suitable donor.

Cooperation between bacteriologist and attending physician is most important.

# EDEMA AS INFLUENCED BY A LOW RATIO OF SODIUM TO POTASSIUM INTAKE

## CLINICAL OBSERVATIONS

M. HERBERT BARKER, M.D.
CHICAGO

The purpose of this paper is to present a few of many observations made on cases of edema which have been influenced chiefly by the dietary mineral control. This material is offered only as evidence of the probable importance of the daily intake of sodium and potassium in the control of chronic cases of disturbed water balance of cardiac and renal origin.

It is not necessary to enter into a long discussion of sodium, potassium, the chlorides and acid-base equilibrium, which have been so ably discussed by Blum, Widal, Bunge, Peters, Van Slyke, Keith and many others included in the editorials of The Journal. It is sufficient to say that there have been repeated statements of the importance of sodium rather than the chlorides in fluid storage and that there is abundant evidence of the antagonistic or the displacing influence of sodium by potassium with a resultant fluid loss. However, no definite program has come out of this great amount of work which has been of real practical clinical use.

Important advances have been made by Haldane, Keith, Gamble, Linder, their co-workers and others who have shown the great influence that acid-forming salts (calcium chloride, ammonium chloride, ammonium nitrate) and the mineral acids (hydrochloric acid) have on base excretion and water balance. The important relation of serum osmotic pressure to edema as influenced by the levels of the serum proteins has been emphasized by Starling, Epstein, Van Slyke, Leiter, Barker and Kirk, Shelburne and Egloff, and others. The rôle played by the motor power of the heart, the quality of the blood and renal function need no emphasis. Realizing that there are many influences concerned in controlling body fluid equilibrium, any one or all of which may be at fault at the same time in an edematous patient, I wish to suggest that a dietary regimen in which the sodium and potassium intake are carefully controlled can be instituted which may bring about an occasional clinical improvement after all other measures seem to have failed.

### EXPERIMENTAL EVIDENCE

In the course of study of experimental edema, the possibility of throwing further light on some of the clinical observations immediately suggested itself.[1] As a result, a series of experiments was planned whereby dogs were made edematous or potentially edematous by reducing their blood serum proteins. Various salts were added to their diets and the most striking of these experiments were those in which sodium and potassium chloride were given.[2] When sodium chloride was added to the diet of such potentially or slightly edematous animals, fluid storage was prompt and often marked (as much as 40 per cent of the animal's weight in five days) and continued as long as sodium chloride was given. If sodium chloride was omitted, the edema would very gradually wear away. If, however, potassium chloride was substituted for the sodium chloride in equal amounts at any period during fluid storage, a prompt and marked diuresis occurred. Similar observations have been made independently by Shelburne and Egloff.[3] Not only would the animals lose all their edema but their weight would run below that of the control periods even though the serum proteins remained at the same levels. When these observations were made and repeatedly confirmed, it became obvious that a clinical application should be attempted.

### CLINICAL SODIUM-POTASSIUM STUDIES

Patients with gross edema were selected for this study. They were chiefly of two classes; first, cases in which treatment had not been given so that they might be considered untreated cases; and, second, those in which all the present-day accepted forms of treatment had been given either without improvement or, if improvement had occurred in the past, with present failure.

The first step taken was to restrict the sodium intake in all its forms, the fluid intake being unregulated. Occasionally, a rather remarkable and prolonged improvement would occur following this one change alone. Going into the diet of these cases, it was found all too frequently that a patient with severe congestive heart failure, although he was on a salt poor diet and taking full doses of digitalis, together with ammonium chloride or ammonium nitrate and diuretics, was allowed at the same time large quantities of citrus fruits, or baking soda for gas and distention, or was given alkaline waters by his physician. It was immediately obvious why the salt free diet, digitalis and the diuretic regimen had failed.

The second step consisted in giving the patient a full maintenance diet of foods which were thought to be adequate in every respect except that the foods containing sodium were restricted when possible, while foods high in potassium were given. It is difficult to get a patient to take a diet for a long period unless it meets the physiologic requirements, and he will find great difficulty in taking any diet without salt. Both objections have been quite overcome by making the diet very liberal and by allowing the patient to shake potassium chloride on his food for taste. To make diets successful in the ambulatory clinic, they must be simple in outline. The plan now in use in the renal clinic at

Northwestern University Medical School is scheduled in tables 1 and 2.

When the diet outlined in the tables is started, 5 Gm. (one teaspoonful) of potassium chloride crystals is placed in a salt shaker in the morning. The patient uses from the shaker all he wishes on his food during the day and at the end of the day places the remainder in water and drinks it. It may be necessary to give more potassium chloride to promote diuresis in obstinate cases of the nephrotic type, but 5 Gm. is ordinarily sufficient in the edemas of cardiac or cardiovascular origin. In a few cases, a rather severe dehydration has resulted, so that the potassium chloride had to be reduced greatly or omitted for a time. Such cases, however, appear to be rare.

TABLE 1.—*Diet: Low Sodium-High Potassium with Acid Excess*

Fruits
  3 servings daily, fresh or stewed, but should include either prunes, plums, cranberries or currants once daily.
Vegetables
  2 large servings daily, especially beets, carrots, brussels sprouts, yellow corn, kohlrabi, lettuce, mushrooms, peas, spinach, kidney beans, *parsnips*.
Meat
  2 servings daily.
Eggs
  2.
Milk
  1 glass.
Cream
  ½ glass.
Butter
  Salt-free, 6 squares.
Cereal
  Oatmeal or wheatena; farina, puffed wheat or rice occasionally.
Bread
  Graham bread, 3 large slices or 6 small slices daily.
Rice, macaroni or spaghetti
  1 serving daily.
Potato
  1 serving.
Jelly, preserves or honey
  2 level tablespoons.
Sugar
  ad libitum—at least 1 tablespoonful.

NOTES

All foods are to be prepared without salt and no salt is to be served with meals. Potassium chloride (from 2 to 5 Gm. in shaker) may be given as salt substitute. Spices—cinnamon, sage, paprika, pepper, cloves, nutmeg, allspice—may be used. Small servings of citrus fruits may be added after fluid volume is established. Additional vitamin D to be supplied.

Coffee or tea, 1 cup daily.

A neutral diet may be obtained in one of the following three ways:
1. Reduction of meat, rice, macaroni, bread, cereal.
2. Increase of fruit and vegetables.
3. Addition of figs, molasses, raisins.

The latter method is recommended.

This diet is designed preferably for the treatment of convalescent and ambulatory patients. Very ill patients will have difficulty in eating all the diet, in which event, the diet may be reduced, the same food substances to be given, but in smaller amounts.

CHEMICAL STUDIES

Frequent determinations of the sodium, potassium, calcium, carbon dioxide combining power, $p_H$ and cholesterol of the blood were done. No attempt will be made to discuss the results of these observations except to state that in general nothing striking appeared.[4] No significant changes in blood sodium or potassium were noted. Certainly there was no potassium storage as measured by increased levels in the blood stream. Tissue sodium and potassium determinations were not made. Occasionally a slight elevation of potassium above the control level of 17 to 19 mg. to a level of 21 to 25 mg. was noted after a few days, but this always fell back to the original level in one or two weeks. Blood serum proteins occasionally were reduced in the edemas of cardiac origin and they would return to normal as the edema reduced. Brown and Rowntree[5] have indicated that hydremic plethora does not exist in nephrotic and cardiac edemas in which there is no anemia, but the frequent apparent concentration of the proteins following diuresis in this group of cases speaks for some dilution. No shift in acid-base equilibrium was noted even after months of such management, which is in contrast to the acid-base balance following the administration of full doses of calcium chloride and hydrochloric acid.

REPORT OF CASES

The following case reports will serve to illustrate the types of patients used in the study and some of the results obtained.

CASE 1.—E. S., a man, aged 56, a manufacturer, came with a history of weakness, dyspnea, orthopnea, irregular heart action, edema and ascites of five years' duration. A past history of chorea, rheumatic fever or syphilis could not be obtained. His symptoms had been slight at the beginning and he had been relieved by digitalis. Later, his symptoms became more severe and he was again quite relieved by taking ammonium chloride. In 1929, he became severely edematous and was forced to give up work. When I first saw him, in July, 1930, he was taking 0.1 Gm. of digitalis leaves three times daily, from 6 to 8 Gm. of ammonium chloride daily, and salyrgan once or twice a week.

The patient was a large man with marked dyspnea, orthopnea, and cyanosis of the lips, hands and lower extremities. He was coughing up large quantities of liquid sputum. The pupils reacted to light and the fundi were not remarkable except for some caliber changes and narrowing of the arteries with nicking at the arteriovenous crossings. The chest was barrel-shaped. There were no signs of fluid, but there was a large amount of moisture all through the bases. The heart was enlarged to percussion, the right border dulness being 4 cm., the left border 13 cm. and the base seemed not to be increased. No thrills were felt, but the apex was forceful. The rhythm was absolutely irregular, with a pulse of 56 and an apex rate of 88. A rough blowing systolic murmur was heard at the apex and transmitted to the base. There were no diastolic murmurs. Abdominal examination revealed a large amount of ascites and a tender liver 8 cm. below the costal margin. The lower extremities showed marked cyanosis and deep pitting edema.

---

[4] The mass of clinical observations and the chemical data accumulated in the study will be published elsewhere.

[5] Brown, G. E., and Rowntree, L. G.: The Volume and Composition of the Blood and Changes Incident to Diuresis in Cases of Edema, Arch. Int. Med. **35**: 129 (Jan.) 1925.

The blood pressure was 156 systolic and 90 diastolic. The blood showed: red blood cells, 4,990,000; white blood cells, 9,600; hemoglobin 77 per cent (Newcomer). The Wassermann and Kahn tests were both negative. The urine showed a specific gravity of 1.018 and a slight trace of albumin, and was acid. The sediment showed an occasional hyaline and granular cast and an occasional white blood cell, but there were no red blood cells. Electrocardiography showed auricular fibrillation with a rather low electromotive force and considerable spread and slurring of the QRS complex. The T waves were inverted in lead 3 and they were regarded as a digitalis effect in that they became upright when digitalis was omitted.

A diagnosis of chronic myocarditis with auricular fibrillation, probably of hypertensive origin, was made, and after five days the patient was placed on the diet low in sodium with normally high potassium. All other medication was stopped, but he was given 5 Gm. of potassium chloride daily to shake on his food. As he had been ambulatory at home, he was discharged from the hospital so that he would be in his most natural state. Two days after starting this regimen, he noted a slight increase in the volume of urine and a decrease in body weight (chart 1). His weight fell from 92 to 75 Kg. in thirteen days and at that time he was entirely free from edema, and his skin hung in folds. Under this marked edema, which he had carried for years, there was rather severe wasting of the muscles. The liver gradually decreased in size and six months later his cough had cleared up and he was back at his work. Now, after a year and a half, he is very active; he feels well and has no cardiac symptoms. About one month after starting the diet he became extremely dehydrated, so the potassium was reduced to 2 Gm. daily and he was allowed small feedings of citrus fruits. He has been more careless of his diet in the past six months but, on the whole, he adheres closely to the plan outlined and seems remarkably well. He has taken 0.2 Gm. of digitalis folia daily during the past six months because the heart rhythm is more regular, but no symptomatic benefit has been observed.

This case seemed to be one of congestive heart failure which had finally failed to respond to management that was above criticism. The patient was apparently taking sufficient digitalis (0.3 Gm. daily) and he was on a low salt diet. He was taking ammonium chloride and finally he was forced to take salyrgan to hold the edema down. The response to the low sodium-high potassium management after a discontinuance of all other forms of therapy was striking. The events are best shown in chart 1. The inset shows a rather sharp concentration of the serum proteins coincident with the loss of the edema.

CASE 2.—M. R., a married woman, aged 27, developed acute nephritis in August, 1929, which subsided, leaving her with an albuminuria of 16 Gm. a day. Four months later (December, 1929) the serum proteins had became gradually depleted, so that she presented the classic symptoms and indications of the so-called nephrosis group. She felt well except that she was tired. Physical examination was negative except for marked pitting edema of the ankles and thighs, and a moderate ascites. The blood pressure ranged about 90 systolic and 55 diastolic. The urea nitrogen of the blood was characteristically low at 8 mg. per hundred cubic centimeters. There was no anemia, and the Wassermann test of the blood was negative. Renal function tests were entirely normal. The urine contained from 12 to 18 Gm. of albumin daily and the sediment was entirely negative except for numerous hyaline casts, a rare hyaline cast with granules and numerous doubly refractile lipoid bodies in the casts and free in the urine. With physical strain or exposure and in the presence of infections of the upper respiratory tract, a shower of red blood cells would be seen in the urine for a few days.

Management consisted of a low sodium-high potassium diet and the protein was increased to 150 Gm. This diet was tolerated very well and she seemed to feel much stronger, but the proteinuria and edema persisted. Eight grams of ammonium chloride daily reduced the edema materially but it failed to keep her free from edema. The same was true of ammonium nitrate in 10 Gm. daily feeding. The sharpest diuresis and the most prolonged effect was caused by giving 4 cc. of dilute hydrochloric acid in water with each meal. However, in all these periods of therapy with the acid-forming salts and the hydrochloric acid, there was an associated decrease in the carbon dioxide, an increase in the chlorides and proteins, and a shift of the $p_H$ from 7.22 to as low as 7.14. When this shift occurred, water was released from the body but the patient complained of not feeling well. She complained of dull headaches, weakness and loss of appetite. No aggravation of the renal picture was noted. Finally, potassium chloride was given in daily amounts of 5 Gm. A sharp diuresis occurred with a loss of all the ascites and the edema. When the potassium salt was discontinued, the fluid gradually returned, and with the resumption of potassium chloride feeding the edema again disappeared (chart 2). The patient was maintained free from edema for weeks at a time by this method.

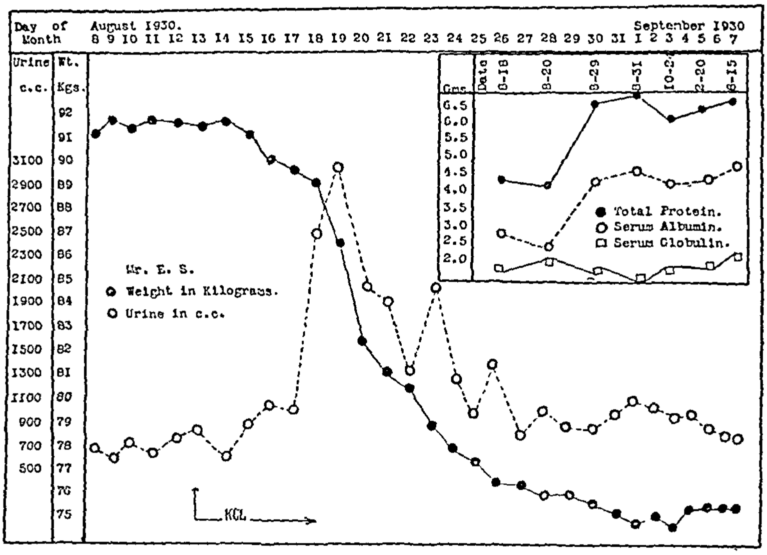

Chart 1 (case 1).—Diet started and 5 Gm. of potassium chloride started Aug. 13, 1930, and continued. The urinary output and the weight loss are graphed. The inset shows a rather reduced total serum protein, chiefly at the expense of the albumin fraction. A quite normal level of 6.5 per cent was found on the 29th after the edema had disappeared. These normal levels have obtained since that time. The last protein levels graphed were determined after one year.

This case is of interest in that the patient presented a nephrotic syndrome which not only responded to the giving of acid and acid-forming salts but relieved her of edema by the neutral salt, potassium chloride. The diuretic influence of large amounts of alkali as given by Osman [6] in this type of case is of interest in that he gives potassium salts in large amounts. Again, an apparent concentration of the serum proteins was associated with diuresis whether it was produced by ammonium chloride, hydrochloric acid or potassium chloride (inset, chart 2). The patient was much more willing to eat the low salt-high protein diet as soon as she was given potassium chloride, which served as a salt substitute as well as a diuretic. It was especially gratifying that the patient had no depressing symptoms while taking potassium chloride, and there were no measurable changes in the acid-base equilibrium, which was in contrast to the acidosis and symptoms produced by hydrochloric acid and the ammonium salts.

---

[6] Osman, A. A.: The Use of Alkalis in the Treatment of Bright's Disease, Guy's Hosp. Rep. 77: 386 (July-Aug.) 1927.

Case 3.—L. L., a laborer, aged 36, began to suffer weakness, dyspnea and nocturia from five to eight times in July, 1931, and later edema of the ankles appeared. The patient had had left hemiplegia in 1925, for which he had been observed in the neurologic clinic. Albumin and hyaline casts were found in the urine and the blood pressure was 225 systolic and 150 diastolic, so he was referred to the renal clinic. Physical examination showed only a slight residual of the old hemiplegia. The pupils reacted sharply to light and in accommodation. The fundi showed edema of the disk margins. The retinal vessels were small and tortuous, and there was nicking at the arteriovenous crossings. No hemorrhages were seen, but there were two small areas of exudation in the inferior temporal quadrant of the right eye. The throat and neck were normal and the chest was clear. The heart was moderately enlarged, the right border dulness being 3 cm. and the left border dulness 13 cm. The rate was regular at 90, and no murmurs were heard except for a slight systolic blow at the apex. The liver was about 5 cm. below the costal margin and it was very tender. There was marked edema of the legs and thighs. The blood pressure was now 196 systolic and 138 diastolic. There was no anemia; the Wassermann reaction was negative and the renal function tests were essentially negative. The day volume was 250 cc. with a specific gravity of 1.022, and the night volume was 1,440 cc. with a specific gravity of 1.012. The phenolsulphonphthalein excretion was reduced to 15 per cent, as might be expected in congestion of the liver. The urea nitrogen of the blood was only 14.5 mg. The electrocardiogram showed a rate of 88, a sinus mechanism, low P waves in all leads and a slurring of the RS complex in all leads. The T wave was inverted in lead 1 and diphasic in lead 2.

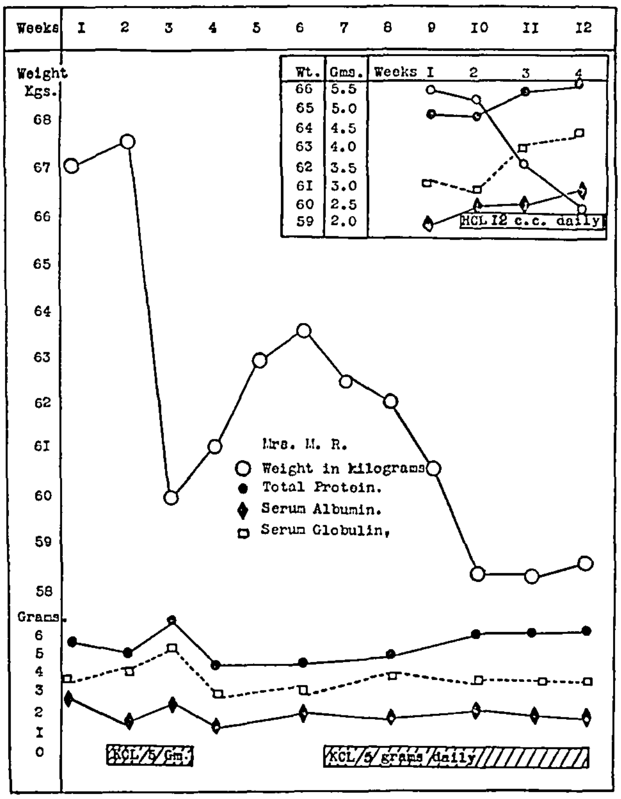

Chart 2 (case 2).—In addition to the diet, 5 Gm. of potassium chloride was given daily beginning with the second week. A great reduction in edema followed as shown by the fall in body weight. The potassium chloride was discontinued and a gradual increase in weight was noted, which again fell to normal when the potassium chloride feedings were resumed. The lines at the bottom of the chart show an increase in the level of the total serum proteins as the edema disappeared. Both serum albumin and serum globulin seemed somewhat increased. The inset shows a similar drop in weight and an increase in serum proteins in one patient associated with the giving of 4 cc. of dilute hydrochloric acid in water with each meal.

The patient was regarded as one having hypertensive vascular disease in which congestive heart failure had developed. He remained ambulatory and continued on the low salt diet of the preceding five years. He was given 5 Gm. of potassium chloride to sprinkle on his food; within a week he noted an increase in the urinary output and a decrease in the dyspnea, and his friends told him that his color was improved. The edema began to disappear rapidly and after two months' time he was quite dehydrated, having lost 30 pounds (13.6 Kg.) (chart 3). He was no longer cyanotic or dyspneic, and he boasted that he was walking two miles daily. He contracted an influenzal type of infection in January, 1932, followed by pneumonia and death.

This patient is of especial interest in that he was known to be hypertensive for six years during which time he had been on a low salt-low protein diet. He had taken no medication except potassium iodide from time to time. He finally developed a typical congestive heart failure from which he seemed to be entirely relieved by taking 5 Gm. of potassium chloride daily (chart 3). No cardiac therapy, bed rest or other circulatory supportive measures were instituted. It was striking to watch the circulatory picture improve as fluid balance was established. The table inserted in chart 3 indicates a rather concentrated state of the serum proteins. A slight return toward normal levels seems to follow clinical improvement.

## COMMENT

To date, sixteen suitable cases have been studied in detail; four of them failed to respond. Clinical differences or laboratory observations have not been determined on which to predict which cases will respond and which cases will not. The cases that have been helped most have been those of congestive heart failure of the nonvalvular type. Two cases of chronic cardiac valvular disease with massive edema have shown good responses. One patient with high-grade mitral stenosis remained edema free for four months and he was up and around, when he suddenly died of pulmonary embolism. The second was a case of stenosis of the mitral and pulmonary valves. This patient was kept edema free for six months and then she went on to congestive failure similar to that present when she was first seen. One severe nephrotic syndrome has been maintained edema free only by the giving of 10 Gm. of potassium chloride daily. The standard care of numerous cases of congestive failure not included in this paper has apparently been greatly augmented by the general plan described.

The diet employed is general and it is felt that it is well adapted to the maintenance of a person with chronic disease. Great care must be given in prescribing diets that are deficient in any way if they are to be taken for a long period of time. This point is not sufficiently emphasized in the clinical literature. Too many patients are placed on unbalanced or deficient diets which render them less able to maintain their body weight during the long strain of chronic disease. In many prescribed diets, it seems that the normal sodium to potassium ratio is greatly disturbed owing to the restricting of meats and the feeding of more fruit and vegetables. In the same fashion a great excess of alkaline ash is introduced into the body, which probably greatly facilitates fluid storage. Lashmet[7] has recently emphasized the addition of acid substances to the neutral diet. It will be noted that the diet outlined in table 2 leaves a definitely acid ash. That may explain why it has rarely been necessary to prescribe acid-forming salts.

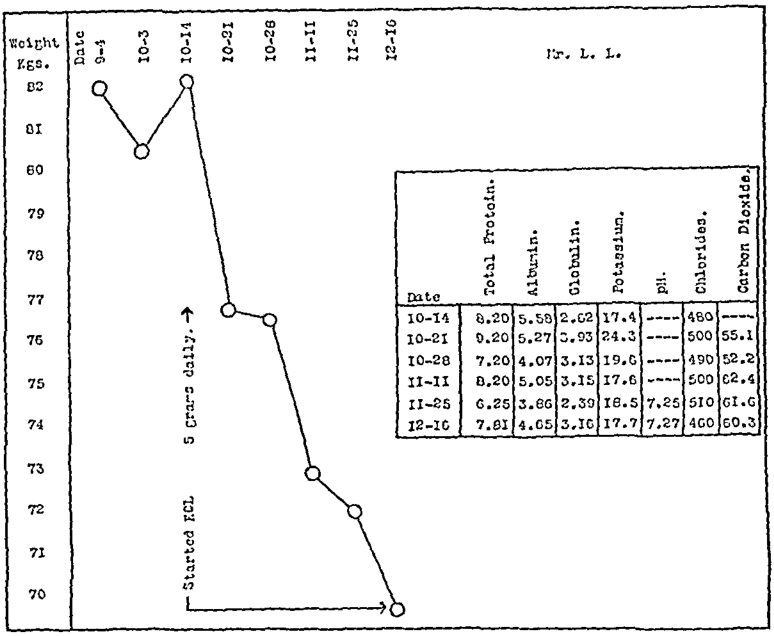
The total amounts of specific mineral given in the diet agree quite closely with the averages given by Sherman[8] in 150 American dietaries. His figures are 1.94 Gm. of sodium and 3.39 Gm. of potassium a day, as compared to 1.07 and 3.33 Gm., respectively, given to our patients. The chief difference is the increased ratio of potassium to sodium, but often no diuretic influence was noted until further potassium was added as potassium chloride. The helpful diet of Keith, Smith and Whelan[9] differs from the plan used in these cases in that they attempt to keep all minerals low. Their first diet contained 3.74 Gm. of potassium, but this was reduced to 1.62 so that all ions were low in amount. The possible dangers of restricting important minerals such as sodium, calcium, phosphorus and potassium is not to be discussed here. The other chief difference is that the Keith low mineral diet leaves an excess alkaline ash.

Although no deleterious effects have been noted in this group of cases in which potassium chloride was given, the extreme toxicity of the potassium ion should be kept in mind. Several observers, Osman,[6] Addison[10] and others, have used large doses of potassium substances over long periods without trouble even in severe cases of vascular and renal disease. However, overdosage and, especially, poor excretion of potassium should be closely watched in that either may result in storage sufficient to produce severe symptoms and death.

In connection with the occasional marked diuretic response to potassium chloride feeding, the work of Harrison and Pilcher and their co-workers[11] should be borne in mind. These workers have shown that tissue potassium is often at a low level in cases of congestive heart failure. Whether or not a relation exists between their observations and the clinical studies presented here will be worked out in the future. The influence of the potassium ion alone or its action in the presence or absence of sodium and in special circumstances or combinations with the chlorides will be answered only by much careful study. Certainly more thought should be given to the minerals ingested by the patient chronically ill with edema.

## SUMMARY

Experimental observations on the relation of sodium and potassium to body fluid balance have been applied to cases of cardiac and nephrotic edema. It has been found that twelve of sixteen patients lost their edema when given potassium chloride, provided they were placed on a full general diet with an acid ash excess in which a low ratio of sodium to potassium was maintained. Some cases responded dramatically and others less. No cause for the success or failure of this regimen has been found. No ill effects from the procedure have been noted in cases followed as long as a year and a half. No conclusions can be drawn from these observations, but it is hoped that this material might be of help to an occasional patient who has failed to respond to the usual measures.



| Date | Total Protoin. | Albunin. | Globulin. | Potassiun. | pH. | Chlorides. | Carbon Dioxide. |
|---|---|---|---|---|---|---|---|
| 10-14 | 8.20 | 5.58 | 2.62 | 17.4 | ---- | 480 | ---- |
| 10-21 | 9.20 | 5.27 | 3.93 | 24.3 | ---- | 500 | 55.1 |
| 10-28 | 7.20 | 4.07 | 3.13 | 19.6 | ---- | 490 | 52.2 |
| 11-11 | 8.20 | 5.05 | 3.15 | 17.6 | ---- | 500 | 62.4 |
| 11-25 | 6.25 | 3.86 | 2.39 | 18.5 | 7.25 | 510 | 61.6 |
| 12-16 | 7.81 | 4.65 | 3.16 | 17.7 | 7.27 | 460 | 60.3 |

Chart 3 (case 3).—This graph shows the dramatic loss of body weight in congestive heart failure, associated with the giving of 5 Gm. of potassium chloride daily when the *sodium intake* was reduced. A complete symptomatic restoration of circulatory efficiency was effected without specific cardiac therapy. The small table inset shows a rather high percentage of serum proteins. The chlorides, carbon dioxide and *p*H remained essentially unchanged.

**Spermatogenesis in Advanced Age.**—Recently I appeared as an expert witness in the law courts in a suit which turned on whether a man of 83 could be the father of a child. We won our case, not only because the collateral evidence was strong, but because I could quote many instances of spermatogenesis in the testes of men of 80 and even of 90. Metchnikoff actually cites the case of a man of 103 in whose testes spermatozoa were found. And if examples are required of the retention of sexual passion we have only to think of Goethe, who at the age of 74 fell so desperately in love with a girl of 17 that when his suit went badly he was prostrated with grief and no longer desired to live. Indeed, it was this episode in his life, and a previous one in which he had been more successful, that suggested to him the theme of Faust.—Walker, Kenneth: The Accidents of the Male Climacteric, *Brit. M. J.* **1**: 50 (Jan. 9) 1932.

## SPONTANEOUS HYPOGLYCEMIC SHOCK IN CHILDREN: REPORT OF FOUR CASES

Herbert L. Elias, M.D., Rockville Centre, N. Y., and
Reuben Turner, M.D., New York

During the past three years, four children have been observed with syncope associated with an idiopathic hypoglycemia. Three patients were admitted with complete loss of consciousness, one with semiconsciousness, and all appeared to be extremely sick. The blood sugar values ranged from 27 mg. to 73 mg. per hundred cubic centimeters. Two of the patients recovered immediately after receiving dextrose intravenously, the third after dextrose by mouth and rectum, the fourth recovered spontaneously. None of these patients had convulsions.

In view of the recent reports in the literature of patients with convulsions due to hypoglycemia, it seems desirable to report this group of cases presenting unconsciousness due to hypoglycemia but not convulsions. There is little reference in the pediatric literature to hypoglycemia as a cause of syncope alone.

Seale Harris[1] was the first to call attention to the possibility of hyperinsulinism in adults as a cause of spontaneous hypoglycemic symptoms. Subsequently several authors reported hypoglycemia associated with hypertrophic disease of the pancreas. Allan[2] in 1929 reported hypoglycemia not associated with any organic disease of the pancreas. Carr[3] has recently discussed the neurologic syndromes associated with hypoglycemia in adults and referred to his interesting case of epilepsy due to hypoglycemia. This patient recovered after the removal of an adenoma of the pancreas. Carr lists the following symptoms of spontaneous hypoglycemia, reported by various authors: weakness, anxiety, restlessness, stupor, diplopia, convulsions, hemiparesis, and automatic behavior.

Josephs in 1926[4] and again in 1929[5] reported a group of cases in which children had convulsions associated with a low blood sugar. In 1929 Griffith[6] attempted to show a relation between the convulsions of early life and hypoglycemia. Others (Talbot,[7] Shaw and Moriarty,[8] Weymuller[9]) have reported low blood sugar values in epileptic patients on a fasting or on a ketogenic diet. It is assumed that the mechanism here was a low sugar intake. No cause for the lowered blood sugar level could be found in our cases. In one case fatigue may have been a factor. Levin[10] has reported low blood sugar values in men after a marathon race.

### REPORT OF CASES

Case 1.—R. B., a white American boy, aged 3½ years, was admitted, Jan. 21, 1931, in a state of unconsciousness of five hours' duration. The blood sugar was 27 mg. per hundred cubic centimeters. He recovered while receiving an intravenous injection of dextrose.

The family history and the past history were negative.

The child had failed to eat his supper eighteen hours before admission, but otherwise he had acted normally until the following morning, when his mother found him lying in bed in a deep stupor from which he could not be aroused. He was brought to the hospital several hours later, still in a comatose condition.

The boy was unconscious. His eyes were slowly oscillating from side to side with alternating internal strabismus, first on the right and then on the left. His neck was not stiff. He had bilateral Kernig and Babinski signs. The throat was injected. The rest of the physical examination was negative. The pulse was 96; respiratory rate, 24; temperature, 97 F.; blood pressure, 88 systolic and 64 diastolic. Examination of the urine showed 2 plus acetone, no sugar, no albumin and nothing abnormal microscopically. The blood sugar was 27 mg. per hundred cubic centimeters of blood with a carbon dioxide combining power of 45 volumes per cent; plasma protein, 4.7; calcium, 8.7; phosphorus, 4.2. The spinal fluid was normal (sugar 12 mg., protein 22 mg.).

While still in the admitting room, after a sample of blood had been taken for examination, the child was given an infusion of 50 cc. of 50 per cent dextrose solution. When about 25 cc. of this solution had been given, the patient was wide awake and crying for his mother. The blood pressure immediately rose to 124 systolic and 60 diastolic. The following day the blood sugar concentration was 86 mg. per hundred cubic centimeters.

The sugar tolerance test is recorded in table 1.

Table 1.—*Sugar Tolerance Test in Case 1*

| Fasting Blood Sugar | 30 Minutes | 1 Hour | 2 Hours |
|---|---|---|---|
| 90 mg. | 121 mg. | 138 mg. | 105 mg. |

Case 2.—J. H., a white American boy, aged 8 years, was admitted July 2, 1930, because of semiconsciousness of four hours' duration. His blood sugar was 53 mg. per hundred cubic centimeters. He recovered slowly after receiving dextrose by mouth and by rectum.

The family history and the past history were negative.

One hour before admission the patient's mother had been hurriedly summoned to the street, where she found the boy in a stuporous condition in the arms of a policeman. She was told that the boy had been frightened by a dog. The patient had had no lunch on the day of admission. He was admitted at about 4 p. m.

On examination he was found to be semiconscious and irrational. Respirations were alternatingly rapid and slow. This irregularity in breathing continued for half an hour after admission. The rest of the physical examination was negative. Neurologic examination, except for semiconsciousness, was negative. The urine showed 4 plus acetone. The spinal fluid was normal. White blood cells, 3,700; polymorphonuclears, 89 per cent; lymphocytes, 11 per cent; blood sugar, 53 mg. per hundred cubic centimeters of blood.

He was given dextrose by mouth and by rectum, and he fully recovered in about six hours after admission.

The results of sugar tolerance tests on two occasions are shown in table 2.

Table 2.—*Sugar Tolerance Tests in Case 2*

| Date | Fasting Blood Sugar | 30 Minutes | 1 Hour | 2½ Hours |
|---|---|---|---|---|
| 7/3/30..... | 56 mg. | 93 mg. | 90 mg. | 93 mg. |
| 7/8/30..... | 87 mg. | 122 mg. | 112 mg. | 63 mg. |

The case showed a low fasting blood sugar preceding the first test but a normal level before a second test five days later.

It is interesting to note that this patient had a slow pulse, whereas a rapid pulse is usually found in patients with hypoglycemic shock.

Case 3.—This case was observed in the examining room. L. R., an Italian girl, aged 11 years, weighing 82 pounds (37 Kg.), had been seen on several occasions because of left facial hemiatrophy, right tibial atrophy and leukoderma following an attack of measles at the age of 2 years.

At the completion of prolonged roentgenologic, physical and anthropometric examinations a sample of blood was drawn

from an arm vein. A few minutes later the child became covered with perspiration and fainted. The pulse was thin and rapid; the skin was cold. The faint lasted about five minutes. The child recovered spontaneously and returned home. There were no previous or subsequent attacks. Examination of blood taken showed the following: blood sugar, 35 mg. per hundred cubic centimeters; calcium, 12 mg.; phosphorus, 5.1; serum protein, 11.2.

Case 4.—J. T., a girl, aged 26 months, was seen in consultation by Dr. Giuseppe Previtali and Dr. Charles Hendee Smith, who kindly permitted us to report the case.

The family history and the past history were essentially negative.

The mother found the baby unconscious, lying in bed at about 8 a. m. The patient was taken to a hospital, where an intravenous injection of dextrose was given soon after admission and immediately after which she regained consciousness. On the next day blood sugar was 73 mg. per hundred cubic centimeters of blood. The urine showed a heavy trace of acetone and a faint trace of sugar. Unfortunately, no blood sugar examination was done before the intravenous administration of dextrose. The blood sugar the next day showed a low normal level.

### SUMMARY

Four patients with attacks of unconsciousness associated with an idiopathic hypoglycemia recovered rapidly following administration of dextrose.

---

## HEMATOMA OF RECTUS ABDOMINIS MUSCLE

Sidney Vernon, M.D., Norwich, Conn.

This case is reported because of its unusual character. Rupture of a blood vessel in the abdominal wall occurred, causing symptoms suggestive of an intra-abdominal pathologic condition.

Mrs. M. R., aged 54, was admitted to the W. W. Backus Hospital, Aug. 21, 1931, complaining of pain in the lower part of the abdomen. She had had a spasm of severe coughing, August 16, which caused a sudden sharp pain in the left lower quadrant of the abdomen. A large globular swelling formed shortly afterward at the site of pain. She remained in bed for four days, but when she arose pain recurred with renewed severity which caused her to seek advice. She was sent to the hospital.

The patient had had a chronic cough for fourteen years, which was painful at times and produced white expectoration. She was married at 18, had twelve children, and passed the menopause at 48. She had had a "fallen womb," which condition was gradually increasing, giving her no great discomfort, however.

The patient was well developed and well nourished. The heart and lungs were normal. Blood pressure was 154 systolic and 90 diastolic. A hard, ovoid mass, the size of a small grapefruit, was felt below and to the left of the midline. Ecchymotic areas about the pubis and perineum, and a marked procidentia with complete eversion of the vaginal wall were present. The abdominal mass did not change its position when the patient turned from side to side but appeared to be adherent to the left side of the abdominal wall.

The patient's temperature, August 21, was 100 F., the pulse rate 110, and respiration 24. Blood count showed 4,400,000 erythrocytes, 70 per cent hemoglobin and 10,400 leukocytes, with 80 per cent polymorphonuclear cells, 12 per cent lymphocytes, 5 per cent eosinophils and 3 per cent mononuclear cells. The urine showed occasional hyaline casts on one examination but none at another examination. Roentgen examination of the chest was negative except for peribronchial thickening probably due to chronic bronchitis.

The patient came to operation, August 26. Under spinal anesthesia a lower midline incision was made and bluish discoloration was noted before the sheath of the rectus muscle was incised. When the sheath was opened a large black clot, which had already begun to undergo hemolysis, presented itself to the left of the midline. The clot displaced the fibers of the rectus muscles. Black clots weighing about 500 Gm. were removed and the cavity remaining was sponged out. Several large veins were seen, which were clamped and tied. The posterior rectus sheath and the peritoneum were then incised and Olshausen suspension of the uterus was performed. The abdomen was closed in layers; a rubber drain was left in the cavity from which the blood clot had been removed. The drain was removed on the third day after operation and a dark serous discharge continued for two days later. The patient made an uneventful recovery and was discharged from the hospital seventeen days after the operation.

### COMMENT

This case illustrates an uncommon condition wherein a hematoma of the abdominal wall occurred not due to direct trauma. It is conceivable that a large vein was ruptured in the violent fit of coughing that occurred. Physical signs noted at the first examination pointed to the condition found at operation.

326 Washington Street.

## MASTOIDITIS WITHOUT APPARENT OTITIS MEDIA IN A PATIENT WITH DIABETES

J. H. Childrey, M.D., and P. A. Gray, M.D.
Santa Barbara, Calif.

Mastoiditis without apparent disease of the middle ear is unusual and its occurrence in a diabetic patient makes the following case doubly interesting:

### REPORT OF CASE

F. S., a white man, aged 27, had had diabetes for ten years. He had taken insulin since 1923.

There was no history of previous ear, nose or throat disease. One month before admission the patient had apparently contracted a slight cold. The next day the left ear felt a little stuffy; later he noted autophony. There was neither earache nor aural discharge. A week later he became dizzy and weak and experienced considerable pain in the left temporal region. A swelling appeared in the left temporal and preauricular regions. This was associated with slight trismus. Two weeks before admission the pain caused him to consult an otolaryngologist, who believed that the condition was a parotitis secondary to an external otitis.

The temporal headache became continuous and more severe; the swelling and trismus increased and the temperature was elevated. A roentgenogram of the mastoid process showed only a slight cloudiness of the cells on the left, but there was no change in the tympanic membrane and no tenderness over the mastoid process, and for this reason the physician hesitated to advise surgery. Because of this infection the symptoms of diabetes became more marked. For a week before admission the patient had vomited all his food and had stopped taking insulin because he could not eat. He was admitted to the diabetic service of Dr. W. D. Sansum at the Santa Barbara Cottage Hospital, Sept. 9, 1931, at 12:30 a. m. in a semicomatose condition. The temperature was 101.2 F., pulse 100, and respiration rate 30 per minute. The breath smelled strongly of acetone; urinalysis showed sugar + + + +, acetone + + + +, and diacetic acid + + + +. Blood sugar was 500 mg. per hundred cubic centimeters. There was an extensive, moderately tender swelling involving the left preauricular, zygomatic and temporal regions of the head. There was no swelling over the mastoid process; only slight tenderness could be elicited by firm pressure in this region. There was no drooping of the posterosuperior wall of the external canal. The tympanic membrane, except for a loss of luster, was normal in appearance. Tests of the hearing showed moderate conduction deafness on the left. Repetition of the roentgen examination of the mastoid again showed a well developed cellular structure, the cells being of the small type. There was considerable increase in density, and trabecular detail was poorly defined, but there was no extensive solution of cell wall integrity. The condition was interpreted as early second degree mastoiditis. The blood picture was as follows: hemoglobin, 75 per cent; red blood cells, 4,830,000; white blood cells, 13,100. Differential count: small lymphocytes, 6 per cent; large lymphocytes, 12 per cent; polymorphonuclears, 82 per cent.

The patient was prepared by appropriate insulin and dietetic management for operation.

Mastoidectomy was performed, September 10, under ether anesthesia. When the cortex was exposed, a small perforation

---

From the Sansum Clinic.

was noted midway between the tip and the spine of Henle. A second cortical perforation was present at the root of the zygomatic process. Approximately half of the cells over a large area were filled with pus, particularly those in the region of the antrum and zygoma. There was beginning destruction of the bony trabeculae. The antrum contained a considerable amount of granulation tissue. Because the inner plate over the sinus and the middle fossa was apparently intact, the dura was not exposed. A huge subperiosteal abscess in the temporal fossa was drained. A rubber drain was introduced into the upper portion of the wound extending to the subperiosteal abscess, and the mastoid wound was packed loosely with petrolatum gauze. The wound was closed with silkworm catgut and dermal. Myringotomy done at the completion of the operation revealed no pus. The drum was healed in a few days without discharging. Culture of the pus obtained at operation revealed Streptococcus mucosus.

September 31, the temporal abscess had to be reopened and drained because the rubber drain had become loosened prematurely. Otherwise, convalescence was uneventful and the mastoid wound healed cleanly.

The patient was discharged, October 14. The urine was sugar free on a maintenance diet with 33 units of insulin daily. The blood sugar fasting was 148 mg. per hundred cubic centimeters. Trismus was almost entirely cleared up and hearing tests showed normal response with both the C and $C_4$ forks.

## COMMENT

Infection of the mastoid process, in which a zygomatic abscess is the principal finding, presents a problem in diagnosis, the difficulty of which is increased in the absence of any apparent disease of the middle ear. That the preceding otitis media was probably slight was shown by the facts that the drum appeared practically normal, that myringotomy disclosed no pus, and that the drum healed early and the function of hearing returned promptly. The infection in the mastoid antrum and cells evidently became walled off from the tympanum by obstruction of the aditus by the firm granulation in the antrum. The early appearance of the cortical perforation and subperiosteal abscess is characteristic of this type of infection and demonstrates the insidious, destructive action of Streptococcus mucosus. The concurrence of diabetes increased the hazard and may have hastened the formation of the subperiosteal abscess.

A review of the literature fails to reveal any report of a case of zygomatic mastoiditis among diabetic patients.

317 West Pueblo Street.

# PIGMENTATION OF THE FACE AND NECK DUE TO FRECKLE CREAM

J. B. Blashill, M.D., Detroit

Goeckermann[1] reported two cases in 1922 of pigmentation of the face and neck which he proved by deductive reasoning to be due to face cream. As to whether the discoloration was a pigment or a metallic deposit, no definite answer was given at that time. In order to show the frequency of such cases, and also to bring out more facts regarding the etiology, the same author[2] reported thirteen additional cases in 1925. At this time he demonstrated by microscopic section the distribution of the pigment in all layers of the skin and subcutis, thus indicating to him that a gradual absorption of the metal took place; also, the pigment in the skin as removed by biopsy was destained by Zenker's solution, which differentiated mercurial deposits from other forms of pigmentation.

Hollander and Baer[3] in 1929 reported a case in which they proved conclusively by a very sensitive electroqualitative chemical method that the discoloration was a metallic deposit. These are the only authors and cases in the literature. I am presenting another such case.

Mrs. G. B., aged 47, a Roumanian, without children, was seen at the clinic, July 22, 1931, for conditions other than the discoloration of the face and neck. However, on seeing the patient come in the door, one was struck by the dark dirty color of the face and neck. On questioning, she stated that she was using "Othine Double Strength Ointment" for the removal of freckles. She had been using the cream for the past year and a half, but no notice of the discoloration was made until a year before admission. The neighbors were the first to notice the change in the color of the face. She then told me that her husband often accused her of having a dirty face and neck. The patient, nevertheless, had kept on using the cream. She stated that she was in the habit of massaging the face and neck with the cream and allowing it to stay on over night. The face and neck were continually becoming more discolored.

The past history is essentially negative. No medicine had been taken or other substances used that might explain the discoloration.

The examination revealed, apart from the facial appearance, two deep rectal fissures and four moles, one of which was situated on the left anterior surface of the neck and which was subsequently removed, another on the forehead over the left orbital ridge, and the other two in the hair line on the posterior surface of the neck. The discoloration was seen to begin on the neck and was rather sharply demarcated. The pigmentation extended on up to include the face and forehead. The posterior surface of the neck was also involved. The face and neck were of a slaty gray with a bluish cast. The color was deeper in the folds of the neck. Although the patient was of Roumanian descent and naturally dark, at a distance the face and neck did look dirty.

Laboratory examinations showed a negative Wassermann reaction, a normal urine analysis, and a very mild secondary anemia (80 per cent).

F. E. Voist, chemist of the Detroit Board of Health, reported that the sample of Othine submitted contained ammoniated mercury and bismuth subnitrate in a cold cream base.

The mole on the anterior left surface of the neck was removed by excision under a local anesthetic. A small piece of skin, 1 by 4 cm., was removed in conjunction with the mole. This was examined both chemically and pathologically. Chemically silver nitrate was used to precipitate the mercury if present. This analysis was negative, probably because the test was not fine enough. The pathologist, Dr. Osborne A. Brines, reported finding many pigment granules in the corium subcutaneous zone of the skin. Because of the position of these pigment granules, one can readily understand how ineffectual treatment would be.

These cases have been confused with many types of diseases, such as, Addison's disease, argyria, exophthalmic goiter, and cardiac and other chronic conditions. The frequency of such cases would be greater if they would not be confused with the conditions just mentioned.

Treatment is of slight value, as has been brought out, because of the situation of the granules deep down in the subcutaneous tissues. Some have advocated the use of a 0.5 to 1 per cent solution of acetic acid, a 0.5 to 1 per cent aqueous solution of potassium cyanide, or weak solutions of iodine rubbed on the skin, followed by removal with alcohol. Some have proposed the use of potassium iodide and sodium thiosulphate internally. Probably the withdrawal of face cream for about six months will be sufficient to show a difference in color, because of the constant absorption that is taking place. Several of the foregoing have been tried with a very gradual clearing up of the skin.

Why one person should become discolored, and another not, is probably based on a difference of susceptibility. I have in mind one person who has been using a triple strength of the same cream for several years, but without any discoloration. This individual, however, does not use it constantly nor does she massage it in and allow it to remain for several hours.

The following points need emphasis:

1. Cases of this type should not be confused with Addison's disease, cardiac disease or other chronic diseases.
2. No treatment is probably any more effectual than allowing the pigment to become absorbed by itself.
3. Susceptibility probably explains why some individuals become discolored and others do not.

# REVIEW OF RECENT STUDIES ON THE ANTINEURITIC VITAMIN

## ITS CHEMICAL AND PHYSIOLOGIC PROPERTIES, AND THE EFFECTS OF ITS DEPRIVATION ON THE ANIMAL BODY

H. D. KRUSE, Sc.D.
AND
E. V. McCOLLUM, Ph.D., Sc.D.
BALTIMORE

[Editorial Note.—The following article is one of a series on the Present Status of the Knowledge of Vitamins, prepared under the auspices of a committee composed of Morris Fishbein, chairman, Lafayette B. Mendel and Julius Hess, representing a joint committee of the Council on Pharmacy and Chemistry and the Committee on Foods. These articles have been considered by the Council on Pharmacy and Chemistry and by the Committee on Foods and are published under their auspices. The opinions expressed are those of the authors and not necessarily the opinions of the Council on Pharmacy and Chemistry or the Committee on Foods.]

For more than a decade the antineuritic principle has been designated as vitamin B, but developments of the past two years have imparted to the latter term an ambiguity that has led to much perplexity. Not only is the chemical nature of vitamin B still unknown, but just what should be included under the term has become largely a matter of individual preference or persuasion. It is not without interest to trace the varied changes which the concept of this vitamin has undergone. What was originally the antineuritic substance of Eijkman and Funk,[1] which was a specific for the cure of polyneuritis in pigeons, and what was the independently discovered water-soluble B of McCollum,[2] which was demonstrated to be necessary for growth in the rat, became merged into the substance vitamin B,[3] following the demonstration that those natural foods curing polyneuritis likewise promoted growth in animals.[4] Thus vitamin B was regarded as one substance, capable of both preventing polyneuritis and furthering growth. But the simplicity of the view was dispelled by convincing evidence that this vitamin actually comprised at least two substances, differentiated on the basis of sensitivity to heat.[5] After a period of utmost confusion in terminology, agreement was finally reached in this country [6] by designating the antineuritic, thermolabile component as vitamin B, and the antidermatitis,[7] thermostable substance as vitamin G. The British, preferring the subscript system, retained the names $B_1$ and $B_2$ for the respective fractions. As the result of this insight into the multiple nature of water-soluble B, there was no longer a water-soluble B growth factor per se; both components, B and G, were deemed necessary for increase of weight in rats.

At once it was appreciated that much of the vast accumulation of facts concerning the distribution, properties and physiologic behavior of vitamin B, recorded when it was held to be a unit substance, would have to be exhumed and reexamined in the light of its dual nature. For the production of uncomplicated vitamin B deficiency, the method now usually involved inclusion of autoclaved yeast as a source of vitamin G in the basal diet. But the provision of vitamin B alone was not so readily achieved because of its instability to heat and because so relatively few foodstuffs contained it to the exclusion of vitamin G. However, by suitable selection of such grains as wheat and corn, which were found to be relatively richer in B than in G, and by taking advantage of the greater solubility of B in strong alcohol, extracts were prepared containing predominantly the B component. With the perfection of this technic, investigations on vitamin B were renewed with an intensity that even yet has only slightly abated. But new complications appeared with the use of moderately refined concentrates of vitamin B, because these products, while curing polyneuritis, very often would not support growth, even when supplemented with a source of vitamin G. So, almost before the novelty of the dual nature of the B complex had worn away, studies with highly purified fractions indicated the possible existence of seven components in the complex, some of which, however, may conceivably be shown later to be identical.

At present there is no adequate nomenclature for these various components, although British practice requires the use of a numerical subscript following the letter B. The situation is made doubly intricate because there is no simple method of differentiating the various factors; it is difficult to dissociate them even by chemical means. Manifestly, in view of the present knowledge concerning the multiplicity of the B complex, an exposition on vitamin B must contain an arbitrary assertion as to just which one of the seven factors is meant. In the present paper we shall regard vitamin B as the thermolabile, antineuritic substance, necessary for growth in both the pigeon and the rat. But such restriction of the term at once impairs the value of the data recorded on the chemical and physiologic properties of the antineuritic vitamin, together with the pathologic changes ensuing from its deprivation. To the disturbing effect of multiplicity on the vitamin B literature may be added the complications arising from inanition, discrepant species requirements, and the divergent criteria of animal tests.

When vitamin B was originally regarded as a growth entity, information regarding its physiologic rôle and the pathologic processes arising in its absence was gathered by the simple expedient of omitting sources of it from a diet adequate in all other respects. Addition of natural foods to such a diet constituted the accepted method of assay for the distribution of the vitamin. By this procedure a tremendous literature on this dietary essential was accumulated. With the acceptance that the vitamin really represented two substances, differentiated by heat, some of the properties previously ascribed to the antineuritic vitamin were shown to be due to the adventitious presence of the second component. Similarly, the multiplicity of vitamin B created erroneous ideas regarding the distribution of the antineuritic component. It is quite clear that when cure of polyneuritis in the pigeon or growth in the rat was obtained, vitamin B was present in the test substance. In the case of negative experiments in the past, however, it was possible that the vitamin B content of foods may have been underestimated because

vitamin G was the limiting factor for growth. When the basal diet for the test of the B growth complex was so supplemented by a source of vitamin G that only the antineuritic B factor was missing, reappraisal of foods for their B values brought some changes. At least foods were now evaluated for their relative richness in B or G.

All such revisory work on the distribution of vitamin B and the physiologic and anatomic consequences of its absence, which have been undertaken with a basal diet supplemented by a source of G, has been assumed to deal with an "uncomplicated vitamin B deficiency." If the claims for the existence of seven factors in the B complex are seriously considered, it is readily seen that in most studies the technic has not been sufficiently refined to permit the production of an "uncomplicated B deficiency." Particularly is this situation encountered in those instances in which yeast provided the G factor in growth experiments; the absence of other thermolabile factors than B may have easily complicated the results. Sufficient evidence has been adduced to indicate that the physiologic and pathologic effects ascribed to the antineuritic vitamin, at least in growth experiments on rats, are in reality the resultant of a multiple deficiency and are subject to revision as the nature of the B complex is amplified. We might be tempted to brand as premature many of the studies on vitamin B in which the effects of a multiple B deficiency have not been eliminated, if it were not for the fact that their potential clinical value outweighs all the fine and academic distinctions that have been emphasized. Nevertheless, in all fairness the exact status of knowledge of vitamin B should be recognized; for the unequivocal production of an uncomplicated vitamin B deficiency cannot in most instances be said to have been established. Obviously, satisfactory studies on the biologic rôle of vitamin B in the strictest sense must await the time when the number of factors in the B complex is definitely settled and when the preparation of concentrates will enable the production of a specific deficiency for each component.

Inanition is the second complication calling in question how much of the recorded morbid anatomy and physiology is rightly ascribable to a deficiency of the antineuritic vitamin. That the presence of vitamin B furnishes a stimulus to the appetite has been convincingly demonstrated by Karr and Cowgill, and by the same token inanition enters as a disturbing element in instances of vitamin B deprivation.[8] It has long been recognized that inanition, whether by direct or by indirect starvation, leads to definite alteration in the physiology of the animal and to a distinct pathologic picture.[9] Just what part of the morbid processes in vitamin B deficiency is due to inanition and what part is due to lack of the vitamin per se has until recently received scant attention. Hence, an imposing group of functional disturbances and anatomic changes have been accepted for years as the effects of B avitaminosis, when in reality they are the manifestations of inanition. It is to the credit of Kon and Drummond[10] that they circumvented the technical difficulties of separating the effects of inanition from B deficiency by feeding an adequate diet to control animals, but at a caloric level equivalent to that consumed by animals on the B deficient diet. In considering the work of the past, they make the sweeping comment that all the pathologic changes observed in beriberi pigeons are directly attributable to inanition.

Another condition that has cast doubt on the interpretation of vitamin B observations has been the use of two species in the animal tests. By far the larger part of vitamin B experimentation has been performed on the pigeon and the rat. Unfortunately the B requirements of these two species for increased weight appear to be widely different. Of the seven components at present advanced as constituents of the water-soluble B complex, the pigeon needs three,[11] and the rat requires five[12] for optimum nutrition. Thus far only one component, the antineuritic vitamin B, has been shown to be definitely needed in common by the two species;[13] on the other hand, there is some evidence that certain components are required by one species but not by the other. The entire question of the nutritive needs of the pigeon and the rat for growth is in a transitional state, and judgment concerning it may well be reserved. It is not impossible that the estimated number of B components may be reduced by the demonstration that certain of them are identical. However, the available evidence that the pigeon and the rat require different components of the B complex for maximum weight is of such convincing character that it cannot be dismissed. Certainly there is abundant opportunity for error in attempting to correlate the pathologic and the physiologic manifestations of the rat and the pigeon on a defective diet: unless the ration of each species is made adequate with respect to all factors required by it, with the exception of the antineuritic component, the observations may not be comparable. The same conditions must be met in assaying foods for their content of the antineuritic vitamin, if the weight test is to be employed. An alternative procedure in assay experiments, strongly advocated by Peters and Smith, is the alleviation of symptomatology specific for polyneuritis in the pigeon[14] or the rat;[15] i. e., the so-called curative test.

The fourth source of confusion with regard to knowledge of vitamin B, particularly of its distribution and properties, has been the lack of uniform criteria in tests. Even with one species, some investigators have used freedom from polyneuritis as the basis of a positive test, while others have chosen to judge success by increase in weight. In general, the B requirements are much more extensive for growth than for treatment of polyneuritis. In the rat, for instance, it has been mentioned that five components of the B complex are thought to be necessary for growth, while only one is needed for prevention or cure of polyneuritis. It is obvious that substances may exhibit antineuritic activity without promoting growth in an animal, because of their deficiency in the additional components necessary for increase of body weight.

Most of the studies on the function and properties of vitamin B and the effect of its deprivation on the body have been open to criticism on one if not all of the foregoing points. Therefore, as the facts concerning vitamin B are presented in succeeding paragraphs, it should be borne in mind that the data in many instances lack the touch of finality, and they should be accepted only with reservation.

### TESTS

For determination of the presence of an antineuritic vitamin in natural foods, extracts and chemically treated fractions, eight possible procedures are open, depending on the animal used, the criteria of the test, and the preventive or curative technic. These procedures can be most conveniently condensed into diagrammatic form:

$$\begin{array}{l}\text{Prophylactic}\\ \\ \text{Curative or}\\ \text{Restorative}\end{array}\left\{\begin{array}{l}\text{Polyneuritis}\\ \text{Loss of Weight}\end{array}\right.\left\{\begin{array}{l}\text{Rat}\\ \text{Pigeon}\end{array}\right.$$

The details of the various methods have been previously presented,[16] and the only essential modification has been the inclusion of a source of thermostable G in the basal diet to render it more specific for antineuritic B. Obviously, in the weight test the basal diet for both the rat and the pigeon will undergo further supplementing in the future for the sake of greater specificity.

### PHYSIOLOGY OF VITAMIN B

In the main, the normal physiology of the antineuritic factor has been learned by study of impaired function or abnormal conditions arising from varying degrees of B avitaminosis. Outstanding among the symptoms of vitamin B deficiency is anorexia. Comparatively early in the study of the B growth factor it was observed that the food consumption of rats was dependent directly on the amount of vitamin B in the diet.[17] This seeming influence of vitamin B on appetite was interpreted as secondary to the more direct effect on growth processes, in which an improved general condition led the animals to raise their level of food consumption to meet the increased needs arising from more rapid growth. However, the desire to partake of food seems to be related directly to the vitamin B intake, because failure of appetite intervenes in vitamin B deficiency and resumption of eating follows separate administration of the vitamin to starving animals.[8] Further, changes in body weight of animals follow food intake; the sequence of events is B deficiency, anorexia, diminished intake, loss of weight. But anorexia from B deficiency is not qualitatively different from loss of appetite due to other reasons; therefore, loss in weight is not pathognomonic of vitamin B deficiency. That the influence of the antineuritic vitamin acts specifically on appetite has been corroborated by restoring a failing appetite by means of a vitamin B concentrate.[18] Which individual component of the B complex is responsible for anorexia has been investigated with results that are equivocal, but it is believed that another component, not vitamin G, is required to supplement the antineuritic B factor in stimulating the appetite.[19]

As might be expected, it was suggested that the striking influence of vitamin B over appetite could be attributed to stimulation of secretion in certain glands, particularly those important in digestion. Accordingly, evidence for the identity of vitamin B with secretin was presented,[20] but eventually this attractive theory succumbed for want of confirmation.[21]

The cause for the loss of appetite occurring with avitaminosis B was then sought in disturbed functions elsewhere in the alimentary tract. From pathologic observations recorded by McCarrison it appeared that vitamin deficiencies induced intestinal lesions, among them degeneration of Auerbach's plexus.[22] The connotation of an effect on intestinal activity appeared to be borne out by the observation of marked intestinal stasis in vitamin B deficient animals.[23] This stasis was attributed, in the chain of reasoning, to gastric and intestinal atony with decreased alimentary rate. By means of a gastric fistula[24] the association of gastric atony with vitamin B deficiency was established; fluoroscopic examination showed hypomotility of the gastro-intestinal tract.[25] Despite these data, the difficulty in demonstrating that diminished gastric tone impairs the appetite was freely admitted; generalized systemic disturbances could as well be responsible for the anorexia. Further, the failure of Kon and Drummond to establish any difference in the alimentary rate between B deficient and normal pigeons seems to indicate that anorexia in the deficient birds is not necessarily connected with impaired motile function of the alimentary canal.[10]

Disturbed digestion has been advanced as a possible explanation of the symptomatology seen in vitamin B deficient pigeons. It was not unreasonable to suspect that polyneuritic pigeons suffered from digestive disorders, because a complete loss of amylolytic and lipolytic,[26] together with a marked decrease of proteolytic enzymes,[27] was reported as characteristic of the birds. Yet, repeated functional analyses on starch and protein digestion in polyneuritic pigeons and rats have invariably failed to show any impairment.[28]

Even the absorptive and assimilatory processes of animals have been assumed to be at fault in B avitaminosis. This theory rests on the anatomic evidence that vitamin B deficiency causes atrophy of the lymphoid tissue of the ileum.[29] Unfortunately, determinations of absorption of dextrose from the alimentary tract have not furnished a convincing answer.[30] In regard to malassimilation ensuing from a vitamin B deficiency, it is not uninteresting to recall Bichel's demonstration that dogs suffering from multiple vitamin deficiencies excreted proportionately more carbon than nitrogen in the urine, leading to an increased

C/N ratio. This condition was attributed to the appearance of partially oxidized carbon compounds in the urine.[31] Of possible significance in this connection was the later separation of a large amount of a lipoidal substance from the urine of dogs on a B deficient diet.[32] The thought was expressed that the fatty substance might be responsible for the increased carbonuria; but, whatever importance this observation seemed to portend for vitamin B physiology was soon seen to be misplaced because the increased urinary C/N ratio has been shown to occur when the diet is deficient, not in antineuritic B, but in the heat-stable component G.[33]

Akin to the hypothesis that vitamin B presides over the activities of the gastro-intestinal tract has been the view that it is necessary for the utilization of the principal types of foodstuffs. On diets with high protein content, for example, nursing young were said not to thrive unless the proportion of vitamin B was commensurately increased; [34] and substantially the same relation was found to prevail for young growing rats.[35] Further, renal hypertrophy results from ingestion of diets rich in protein but low in the antineuritic substance, according to Reader and Drummond.[36] But, again, vitamin B has apparently been credited unwittingly for a function exerted by another component; the protective factor rendering high protein diets adequate for growth has now been characterized as alkali-stable [37] and heat-stable.[38] It should be mentioned that any ration of high protein requiring liberal amounts of vitamin B is at variance with Funk's views, who holds that high protein demands less B.[39] More recently the increased B requirements of rats on high protein diets has not been corroborated, Renal enlargement occurs on high protein diets regardless of the content of vitamin B,[40] and during the growth period at least the B requirement of the rat is not influenced by protein intake.[41]

Curiously enough, Hopkins [42] has noted that a moderate excess of cod liver oil is often injurious to rats unless "balanced" by an increased marmite (yeast preparation) allowance. Indeed, an increase of cod liver oil concentrate necessitates a pro rata addition of vitamin B, if the animal is to escape death.[43] It was suggested that between vitamin A and the B complex exists an antagonistic relation. The striking feature about animals given large doses of cod liver oil, even in the presence of adequate yeast, is their manifestation of symptoms resembling those of a vitamin B deficiency; the condition is alleviated by further increments of yeast.[44] Moreover, certain amines found in cod liver oil produce the same effects seen in B avitaminosis. That the toxic action of cod liver oil may, therefore, not be due to hypervitaminosis is a valid possibility.

Considerable attention has long been attracted to the place of vitamin B in carbohydrate metabolism. Because of the more rapid production of polyneuritis by carbohydrate-rich diets, the necessity of the antineuritic vitamin for utilization of carbohydrates was early emphasized.[45] Yet unhappily the evidence dealing with such a purported relationship has been so consistent in its contradictions that it almost defies a decision. Whereas in one instance the respiratory quotient failed to rise following the injection of dextrose into polyneuritic animals,[46] in another instance the quotient increased slowly but definitely.[47] Again, dextrose tolerance remained undisturbed in B deficient animals, it was asserted by Eggleton and Gross,[48] while diminished tolerance definitely characterized the moribund state of animals of other investigators.[49] As corroborative evidence that vitamin B actually does participate in carbohydrate metabolism, the presence of a hyperglycemia in polyneuritic pigeons has been repeatedly reported; [50] but the complication of inanition has so confused the results that present interest centers on acceptable technic to the neglect of the major issue. It now appears that the course of events for both rats [51] and pigeons [52] on B deficient diets is a hyperglycemia during the greater part of the deficiency period, followed by a hypoglycemia in the moribund stage due to a reduced metabolism. Since starving pigeons likewise show a hyperglycemia [52] which cannot be altered by administration of B concentrates,[53] it seems highly probable that the hyperglycemia in polyneuritic pigeons is the manifestation of inanition.[10] On this basis the normal sugar values reported by Stucky and Rose for dogs on B deficient diets indicate that their animals were not yet suffering from inanition.[54]

In line with the view that a lowered blood sugar represents the true terminal picture of B avitaminosis, Sure and Smith assert that when the maternal diet is deficient in the antineuritic B factor the nursing young show either a progressive hypoglycemia or a slight hypoglycemia followed by a precipitous drop in the premortal stage.[55] Under these conditions, vitamin B therapy produces a rapid increase in the concentration of blood sugar. In their studies on the blood sugar values of weaned and adults rats, they employed a method for determining sugar which removed nonfermentable reducing substances, thus providing data on true as well as apparent sugars. They found in antineuritic deficiency a rise in nonreducing sugars; on the other hand, no disturbance in the concentration of true sugar occurred until the later stages of avitaminosis.[56]

Another bodily function that has been supposed to undergo change in vitamin B deficiency is oxidation. Lowered oxygen consumption has been described for polyneuritic tissues,[57] but repetition of the work by other investigators has shown only normal oxidative capacity for muscle tissue from B deficient pigeons, even when the bird was moribund.[58] Yet it seemed advisable to test the oxygen requirements of the intact animal in want of the antineuritic substance, because conceivably the tissues might have normal oxidative agents while the whole body for some reason was showing a lowered gaseous exchange. This contingency was not borne out on investigation; the mechanism for cellular oxidation was unimpaired in the deficient birds, and the low values obtained in the final stages were comparable to those seen in inanition with exhaustion of food reserves.

The most recent developments in this phase of vitamin B physiology are of unusual interest. Directly in opposition to the observations recorded in the foregoing paragraph, fresh evidence now implicates the oxidative processes for responsibility in the neurologic disturbances of polyneuritis. According to Kinnersley and Peters,[59] pigeons showing symptoms of opisthotonos in the terminal stages of avitaminosis B have an increased amount of lactic acid in their brains. This accumulation of lactic acid is concomitant with neurologic symptoms in avitaminosis B, and it disappears within a short period after vitamin B therapy. Quite naturally, the mechanism of increase of lactic acid in the brain next excited inquiry. Available data indicated that it was the consequence not of a hyperglycemia but of a lacto-acidemia. But the importance attached to the blood-lactic acid in the process was short lived. Careful search in the brain to ascertain whether the increased lactic acid content was diffuse or focal in its distribution revealed that the acid accumulation was localized largely in the lower part.[60] Such a distribution restricted to one region indicated that no direct relation existed between the lactic acid of the blood and that of the brain; but it did suggest some localized abnormality, perhaps an oxidative deficiency in a small area, not detectable grossly in studies on the brain in toto. True to presumption, a lowered power of oxygen uptake was found in the brain, with the exception of the cerebellum, of pigeons with impending polyneuritic symptoms.[61] An enzyme deficiency was cited as the cause. But Guha [62] prefers to believe that the lactic acid accumulates in foci of the brain, owing to interference with its synthetic rather than its oxidative removal. Dissenting somewhat from all these details, Vogt-Møller [63] has expressed the view that the symptoms of B avitaminosis are caused by intoxication with accumulated methyl glyoxal rather than lactic acid. He attributes an increased methyl glyoxal concentration to a deficiency not of glyoxalase but of a co-enzyme.

As Drummond has emphasized, many of the abnormalities exhibited by animals deprived of vitamin B, such as lowered body temperature and respiratory metabolism, loss of weight, and hyperglycemia, are the result of inanition arising from anorexia rather than from a specific deficiency of the antineuritic vitamin per se. True vitamin B deficiency is characterized by anorexia and convulsive seizures associated with focal accumulation of lactic acid in the brain. At this point it is pertinent to mention that rats depleted of vitamin B during their nursing period are definitely inferior in maze learning to normal rats.[64] The offspring of the depleted animals, however, are able to attain the normal level of learning ability, provided they are raised on a diet rich in vitamin B complex. Whether impaired mental processes have a basis in the local increase of lactic acid in the brain is an engaging item for speculation.

To the list of true symptoms associated with B avitaminosis, Drury and his co-workers [65] would make an addition; namely, severe bradycardia, not ascribable to inanition, and relieved at once by administration of vitamin B. Then, too, other functional disorders have been described in animals suffering from lack of the antineuritic principle. As regards the reproductive system, females show delayed sexual maturity and a definite disturbance in the estrous cycle, whereas males manifest a lessened sexual interest, although the anatomic and functional integrity of their germinal elements is unaffected.[66]

In the blood, changes in both cellular and chemical content have been charged to vitamin B deficiency. Disturbance in the hematopoietic function, associated with anhydremia, is said to occur in B avitaminosis, but the anhydremia is attributed to inanition.[67] Lymphopenia in the absence of leukopenia also occurs in vitamin B deprivation.[68] Considering changes of the usual chemical constituents of the blood and tissues, we find that polyneuritic rats, whether in the nursling, growing or mature age, show no lowering of alkali reserve.[69] Nurslings on B deficient diets are subject to extreme decrease of liver glycogen.[70] In lactating mothers, nursing young, and weaned animals there is marked lipemia, in which lecithins, fatty acids, and the iodine number of the fatty acids are markedly increased.[71] Attempts to correlate the convulsive seizures of B avitaminosis with low blood calcium have been uniformly unsuccessful.[72]

### PATHOLOGY

In the past, almost all pathologic records on polyneuritic pigeons have listed, as typical of the results of vitamin B deficiency, the following anatomic changes: nerve fibers in varying stages in degeneration; atrophy of the thymus and voluntary muscle; enlargement of the heart and suprarenals; atrophy of mucous and muscular layers of the gastro-intestinal tract, together with an enteritis; and degeneration of the mesenteric plexus of Auerbach.[73] In accord with these observations, histologic examination of both the central and the peripheral nervous system in B deficient dogs has revealed a myelin degeneration patchily distributed in the vagus, brachial and sciatic nerves, and in the focal degenerative lesions in the cerebrum and pons.[74]

However, reexamination of the tissues of B deficient animals under more carefully controlled conditions has brought an altered conception of the pathology specific for B avitaminosis. Because of the slight nerve degeneration in polyneuritic birds, and because of the remarkable promptness with which vitamin B alleviated the neuritic condition, Schnyder [75] could not believe that the nervous symptoms resulted from degenerative changes in the nerves. Moreover, Kon and Drummond [10] assert that there is little neurologic ground for supposing that head retraction in polyneuritic pigeons depends on changes in the nerves of neck muscles; for they saw large numbers of normal fibers and endings in the intermuscular nerves. What is even more cogent, they confirmed Woollard's [76] view that starvation and cachexia are largely, if not entirely, responsible for the nerve changes seen in vitamin B deficient pigeons. In reiterating Schnyder's conclusions, they said: "No nerve regeneration is possible in the course of a few hours, so nervous symptoms, vanishing so rapidly under action of vitamin B, must be due to a quite different cause."

In his original report, McCarrison [22] described hypertrophy of the suprarenal glands and increased output of epinephrine not only in B deficiency but also in inanition. In addition to confirming the hypertrophy of suprarenals in beriberi pigeons, Beznak [77] could find no enlargement in starving pigeons receiving only vitamin B. In his opinion, suprarenal hypertrophy was specific for B deficiency. After weighing the contradictory evidence, Drummond and Marrian [51] straddled the question by pointing out that the hypertrophy "is not characteristic of vitamin B deficiency, unless starvation be regarded as a form of this disorder." Thereafter, Kon and Drummond [10] tended to subscribe to Beznak's view that the suprarenal enlargement was due specifically to avitaminosis B, but they called attention to the inadequacy of their data. Further investigation, however, failed to substantiate their preliminary results, since the hypertrophy, occurring in the late stage of starvation, was not prevented by extracts rich in vitamin B.[53] Finally, new evidence led Marrian to return virtually to Beznak's stand, except that a deficiency of the two factors, B and G, was believed to play a part in the enlargement of the suprarenals, the vitamin B deficiency being the more important.[78] It was stated that the cortex is the site of suprarenal hypertrophy in most cases of B deficiency, the medulla being involved when starvation complicates the picture.

In rats stunted by deficiency of vitamin B, body form is different from that of normal animals of the same age.[79] In proportion to body length, the deficient animals have smaller chests and longer bones of all extremities. Moreover, they have bone lesions that are essentially identical with those seen in guinea-pigs suffering from acute and uncomplicated scurvy.[80] Marrow elements are destroyed and replaced by reticular tissue supporting widely dilated, congested blood vessels. Hemorrhages may occur later. Similarly, nurslings succumbing to B deficiency show hemorrhages in the osteogenic tissues, particularly near the occipitoparietal sutures.[81] High protein or low protein plus glycine and alanine, with an inadequate amount of vitamin B, is said to produce atrophy of the thymus and hypertrophy of the thyroid in adult rats.[82] In the same species suprarenal glands are enlarged as the result of either B or G deficiency, but the greater degree of hypertrophy under the latter condition is ascribed to the longer survival period.[83] Atrophy of both the spleen and the thymus has been reported.[84]

### BODILY REQUIREMENTS OF VITAMIN B

It is believed that the vitamin B requirements are increased during lactation, but the view is by no means generally accepted.[85] In studies on the physiology of the mammary gland, McCollum [85] found that vitamin B passes into the mother's milk only when it is present in her diet. According to Macy, lactating rats fed human milk as a source of vitamin B at a level previously ascertained to be adequate for growth and reproduction showed unsuccessful lactation, in that there was a high mortality of nursing young and those surviving were much debilitated. The adverse conditions could be alleviated by addition of yeast to the diet of the mother. It was determined that the vitamin B requirement of the lactating rat is from three to five times its growth need. The increased requirement of the antineuritic vitamin for successful mammary function is due to the inability of the lactating mother to secrete the vitamin quantitatively in the milk. Whether the antineuritic factor is the only component of the B complex, which must be furnished in liberal amount to the lactating rats, is a matter in which there is a difference of opinion. Evans advises that the additional B required in the maternal diet may be supplied just as successfully by antineuritic B concentrates as by yeast; therefore, the animal needs a surplus of B, not G. Contrary to that conclusion, Sure adduces evidence that B and G are the limiting factors in lactation, and that proportionately greater amounts of each are necessary for normal lactation, in contrast to growth. In this stand, Sure was confirmed by Husseman and Hetler. In contrast to the question of how many components of the B complex are involved in the magnified needs of lactation is the belief that an insufficiency of the B complex is in no way responsible for unsuccessful lactation. Although superheated milk as the source of B in the maternal diet failed to support lactation, Daniels saw no symptoms indicative of a B deficiency in the nursing young. Rather, she attributed the debilitation of the nursing young to the inability of the maternal rat to ingest sufficient milk to meet the caloric requirements; i. e., poor mammary function was a matter of inadequate milk secretion instead of a qualitative deficiency in B. Waddell subscribes to this interpretation, but Sure takes issue on the basis of technic. In the same vein of skepticism regarding the direct relation of vitamin B to lactation, the argument has been presented that lactating rats on diets deficient in B consume approximately 50 per cent less food than do those on the same rations fortified with an abundance of B. The inference is obvious. But the use of the paired feeding method, in which control animals on an adequate diet are limited in their caloric intake to the same level recorded for the experimental animals on the B deficient diet, has shown that the antineuritic vitamin exerts a specific action on lactation, unrelated to the plane of nutrition.

Nothing better reflects the unsatisfactory nature of our knowledge concerning the function of vitamin B than the number and variety of theories pertaining to its purported rôle in metabolism.[86] That protection against the deleterious effects of high protein or the toxic nitrogenous bases in fish oils necessitates a commensurately high level of vitamin B has already been mentioned. On the other hand, Funk in his early work maintained that the greater the amount of protein, the less the amount of vitamin B necessary in the diet; in fact, he assumed that protein exerts a sparing action on the antineuritic factor. Further, since carbohydrate diets seemed to induce polyneuritis more rapidly, he concluded that vitamin B requirements rose *pari passu* with increasing amounts of carbohydrate in rations. As a baffling example of diametrical results, Funk announced that excess of fat caused a nutritional disturbance in rats; whereas Evans furnished evidence that an excess of certain fats exerted a sparing action on vitamin B.

Aside from the effect of large amounts of protein, fat or carbohydrate in the diet, the condition of an animal with respect to its age, weight, and energy level is significant in fixing its vitamin B requirement.[87] Although Daniels holds the view that the vitamin B requirement per unit of body weight is higher in early infancy than later and decreases with age, most investigators agree that there is a quantitative relationship between the antineuritic vitamin and growth which reflects a greater need for B as the animal progresses through the growth period. It has been suggested that the amount of vitamin B necessary for successful nutrition is directly proportional to the calories consumed, but this view has met vigorous objection. In relating the B requirements of an animal not to one circumstance, but to both weight and caloric level, Cowgill has translated the animal's needs into terms of a comprehensive, mathematical formula.

### DISTRIBUTION

With the knowledge that vitamin B in the older sense is a complex comprising several factors, the evidence for the wide distribution of the antineuritic component, based on positive tests in the past, remains unchanged. But refined technic has shown the relative concentration of B as contrasted with G in a variety of foodstuffs. Oats, corn, wheat, wheat embryo, the outer layers of rice, rice polishings and red kidney beans are relatively richer in the antineuritic B component than in G;[88] while milk, egg-white, banana and cooked fresh spinach have a preponderance of G.[89] That yeast is an excellent source of both factors has been amply demonstrated,[90] but quantitative tests on several samples have revealed that the concentration of B varies considerably, while the G content is relatively uniform.[91] Owing to the variability of the B content, vitamin G may be the limiting factor in yeast as often as B. The relative concentrations of the B and G components in both leafy and root vegetables have been assayed by Roscoe with profitable results.[92]

### PROPERTIES

Recent work on the properties of vitamin B has been essentially a confirmation of data already recorded. The antineuritic vitamin is soluble in water and in alcohol of concentrations from 83 to 93 per cent by weight, whereas vitamin G is insoluble in 95 per cent alcohol, only appreciably soluble in 80 per cent alcohol, and its solubility becomes greater as the proportion of water in the alcohol-water mixture is increased.[93] Vitamin B is insoluble in chloroform, carbon tetrachloride, ether, acetone, and ethyl acetate. As is well known, the antineuritic vitamin is susceptible to destruction at high temperatures, the extent being dependent on the temperature, time and conditions of exposure; it is likewise sensitive to alkalis to a degree determined by the temperature, time and strength of the alkali.[94] Autoclaved yeast has been generally used as a source of vitamin G under the impression that the B component had been largely destroyed, but Williams and his associates assert that autoclaving brewers' yeast at 15 pounds steam pressure for six or even twelve hours does not insure complete destruction of the vitamin B present.[95]

The maximum adsorption of antineuritic B on fullers' earth occurs at $p_H$ 4, according to Salmon.[96] That B is adsorbable both by animal charcoal and by silica gel has been maintained, but Evans was unable to demonstrate the adsorption of B on either substance.[97] When Hogan and Hunter asserted that the vitamin B complex exposed to a quartz mercury arc suffered destruction of G but retained its antineuritic activity, high hope was held of obtaining a pure source of vitamin B.[98] The consensus is, however, that ultraviolet irradiation exerts a destructive action on both the B and G factors, with the velocity of reaction greater for the G component.

In 1918, McCollum and Simmonds indicated that the action of nitrous acid on vitamin B left its growth-promoting properties intact. In the light of present views on the multiplicity of the vitamin, the implication is that all components of the B complex are resistant to diazotization.[99] But recent work has raised the question whether the complex is inactivated by the nitrous acid, and if so, what component suffers. Two of the British investigators, using the curative pigeon test which is specific for antineuritic B, say it is not destroyed. Reversing his previous position, Levene states that the B complex is inactivated, as a result of the destruction of the activity of vitamin G. His results, however, were not corroborated. The present trend is to the belief that drastic treatment with nitrous acid may inactivate the B component, but the destruction is attributed to side reactions. Vitamin G is regarded as being even less susceptible than B to the action of nitrous acid.

The antineuritic substance dialyzes freely through cellophane and collodion membranes; and it migrates under the influence of an electric current, behaving as a base in such experiments.[100]

### ISOLATION

All concentrates, and even crystals, of the antineuritic vitamin thus far prepared have been shown to be contaminated by the presence of other components of the B complex. It is gratifying, however, that investigations of the past four years on the isolation of the antineuritic factor have been extremely fruitful, so that it seems improbable that the identity of this substance can remain hidden much longer. Very potent B fractions have now been separated. For example, Seidell has prepared a concentrate which in doses containing 0.15 mg. of nitrogen protected pigeons from loss of weight on a diet of polished rice.[101] Peters pointed out that the maintenance requirements of the pigeon demand the presence of three B factors; hence, Seidell's concentrate must be composite.[102] By further purification Seidell obtained his most active product, which was capable of (1) relieving polyneuritis in rats in 0.05 mg. doses, containing 0.0062 mg. of nitrogen; (2) preventing loss of weight in pigeons on a polished rice basal diet in alternate day doses of 0.2 mg., containing 0.025 mg. of nitrogen; (3) promoting growth in rats in doses of 0.1 mg. daily as the sole source of the antineuritic component, when supplemented with vitamin G.[103] His most active samples contained from 10 to 13 per cent of nitrogen, about 6 per cent of organically bound sulphur, and did not give the Pauly reaction.

Using cure of head retraction in polyneuritic pigeons as a positive test, Kinnersley and Peters reported that their active preparations gave a Pauly reaction, a positive qualitative test for sulphur, a positive Molisch reaction, and a negative Benedict reaction.[104] Since their purified "torulin" would not afford maintenance in pigeons, it was regarded as a more refined product than Seidell's concentrate.[102] By use of fractional precipitation with phosphotungstic acid, they prepared an antineuritic concentrate active in curing head retraction in pigeons in doses of 0.012 mg.[105]

In 1926, Jansen and Donath announced the isolation of crystalline material which in daily doses of 0.003 mg. protected bondols (rice-birds) against polyneuritis.[106] According to Eijkman, 0.2 mg. doses of the material cured polyneuritis in pigeons.[107] Analysis of the free base gave figures corresponding to the formula $C_6H_{10}ON_2$; no mention was made whether the substance contained sulphur. Their crystals gave a positive Pauly's diazo reaction, and a positive test with the Folin-Macallum uric acid reagent.

Guha and Drummond[11] repeated Jansen and Donath's work, using wheat embryo instead of rice polishings as the starting material. They obtained a final gold precipitate and gold filtrate which were inactive in the cure of polyneuritic pigeons in doses of 0.028 mg. and 0.038 mg., respectively, but were active in combination in much smaller doses; namely, 0.014 and 0.019 mg. They felt that the action of antineuritic B probably could be ascribed to more than one factor. The gold precipitate gave both color reactions noted for the Jansen and Donath crystals.

Repeating the Jansen and Donath process with minor modifications, Williams and his co-workers did not obtain crystals, but they observed that the relative distribution of activity in the various fractions corresponded roughly with that in the original work.[108] They also tested vitamin hydrochloride crystals, furnished by Jansen and Donath, on pigeons fed a basal diet of polished rice; in doses of 0.04 mg. daily, the crystals retarded the appearance of polyneuritis and death but did not prevent the loss of weight in the birds.

Williams was "disposed to take Jansen and Donath's claims of isolation seriously." Employing the curative test on the rat, Seidell and Smith likewise tested the Jansen and Donath crystals and found that the smallest effective dose was 0.04 mg., containing 0.0069 mg. of nitrogen, which amount indicated a potency comparable to that of Seidell's concentrate.[103]

Kinnersley and Peters applied the Jansen and Donath method to some yeast fractions without success.[109] They were inclined to attribute their failure to some peculiarity of yeast extracts, a speculation borne out by Williams' similar experience with yeast. Later they were supplied with Jansen and Donath's crystals, and they noted that the crystals and torulin each gave a positive Pauly test.[110] Tests of the crystals by the curative pigeon and rat methods yielded the following positive results: pigeon, 0.007 mg. daily by injection; pigeon, 0.009 mg. daily by mouth; rat, 0.005 mg. daily. They stated that the crystals were not pure but contained another component of the B complex.

# *The Chemical Laboratory*

THE FOLLOWING IS A REPORT BY THE AMERICAN MEDICAL ASSOCIATION CHEMICAL LABORATORY. P. N. LEECH, Director.

## EXAMINATION OF ETHYLENE FOR ANESTHESIA.—V

The control of anesthetic agents requires vigilance by both manufacturers and standard-enforcing agencies. Even though impurities may be slight and relatively harmless, in anesthesia the purest product obtainable should be employed. For this reason the U. S. Pharmacopeia has required high standards for ether. One who follows carefully the Notices of Judgment of the Food and Drug Administration cannot help but appreicate how alert the government has been in enforcing these standards. Pharmaceutic manufacturers have also made large expenditures investigating the keeping qualities of ether.

Ethylene is a relatively recent addition to the agents employed widely for general anesthesia. It is not described in the Pharmacopeia and therefore does not directly concern the Drug Administration of the U. S. Department of Agriculture. When ethylene first came on the market, the Council on Pharmacy and Chemistry requested the A. M. A. Chemical Laboratory to establish standards for this substance. Not only has the Laboratory established suitable standards but, because of the nonofficial status of the gas, frequent examinations[1] have been made of the market supply of ethylene. Recently there was submitted to the Council on Pharmacy and Chemistry a new brand of ethylene. It was deemed advisable at the same time this product was examined chemically to purchase market supplies of the other products described in New and Nonofficial Remedies. Accordingly, tanks of ethylene for anesthesia were purchased both in Chicago and in Columbus, Ohio. In this work the A. M. A. Chemical Laboratory again secured the cooperation of Dr. Warren R. Smith, head of the Department of Chemistry at Lewis Institute, Chicago. The results of the examinations of ten cylinders of ethylene are given in the accompanying table.

| Brand | Source | Cylinder No. | Percentage Not Absorbed by Bromine Water | Indicated Percentage of Ethylene | Carbon Dioxide | Carbon Monoxide | Acidity or Alkalinity | Impurities by Silver Ammonia Hydroxide |
|---|---|---|---|---|---|---|---|---|
| Cheney | Chicago | 20771 | 1.1<br>1.1 | 98.9<br>98.9 | 0 | 0 | 0 | 0 |
| | Columbus | 78314 | 1.2<br>1.2 | 98.8<br>98.8 | 0 | 0 | 0 | 0 |
| C. L. P. | Chicago | 17405 | 1.2<br>1.2 | 98.8<br>98.8 | 0 | 0 | 0 | 0 |
| | Columbus | 16767 | 1.6<br>1.6 | 98.4<br>98.4 | 0 | 0 | 0 | 0 |
| Lennox | Chicago | 18337 | 1.1<br>1.1 | 98.9<br>98.9 | 0 | 0 | 0 | 0 |
| | Columbus | 25939 | 1.0<br>1.0 | 99.0<br>99.0 | 0 | 0 | 0 | 0 |
| Puritan | Chicago | 29052 | 0.5<br>0.5 | 99.5<br>99.5 | 0 | 0 | 0 | 0 |
| | Columbus | 20859 | 0.6<br>0.6 | 99.4<br>99.4 | 0 | 0 | 0 | 0 |
| Walco | Chicago | 1603 | 1.0<br>1.0 | 99.0<br>99.0 | 0 | 0 | 0 | 0 |
| | Mfr. | 1563 | 0.90<br>0.95 | 99.1<br>99.05 | 0 | 0 | 0 | 0 |

The products examined were found to comply in all respects with requirements given in New and Nonofficial Remedies for ethylene for anesthesia.

### CONCLUSIONS

1. Ten cylinders, representing five brands of ethylene for anesthesia, were recently examined by the A. M. A. Chemical Laboratory. All specimens examined conformed to the standards accepted for New and Nonofficial Remedies.

2. Physicians have a wide choice in acceptable brands of ethylene for anesthesia. All the firms listed[2] test their products according to the methods worked out by the A. M. A. Chemical Laboratory and included in New and Nonofficial Remedies. A statement of chemical investigation according to these methods should be requested by physicians with each tank of ethylene purchased.

# *Council on Pharmacy and Chemistry*

## PRELIMINARY REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT W. A. PUCKNER, Secretary.

### TRIETHANOLAMINE

Triethanolamine, having the formula $(C_2H_4OH)_3N$, is a colorless, viscous liquid with a slight ammoniacal odor, very hygroscopic, miscible with water, imparting a strongly alkaline reaction to the solution. According to Marlin T.-R. Maynard, Triethanolamine: An Adjunct to Dermatologic Therapy (*Arch. Dermat. & Syph.* **25**:1041 [June] 1932), triethanolamine is an excellent emulsificant; it has an antiseptic and penetrating power, and when added to certain preparations used on the scalp, for example, oil of cade, it makes them more easily removable. It is intended for external application only.

Triethanolamine is supplied by the Carbide and Carbon Corporation, New York (unit of Union Carbide and Carbon Corporation), which firm has supplied a specimen of the product to the Council, and a statement of the amount of mono-ethanolamine, diethanolamine and triethanolamine contained in the product as marketed. The specimen and the standards are being studied by the A. M. A. Chemical Laboratory.

Since triethanolamine gives promise of being a desirable addition to the armamentarium of the dermatologist, the Council directed publication of this preliminary report in the hope that this might encourage work which shall bring out confirmation of the reputed advantages of the drug.

## REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. W. A. PUCKNER, Secretary.

### MEDICATED CORN PLASTERS

So-called medicated corn plasters which are offered for general use by the public contain in general a caustic agent such as salicylic acid as their potent component.

The Council feels that the indiscriminate use of corn plasters containing salicylic acid by the public is not without some danger. The public is too prone to consider any lesion on the foot, especially if it is somewhat indurated, as a corn; the next step, without consulting anybody or getting medical advice, is to go to the drug store, get a corn plaster, and start its use. With the corn plaster ordinarily a razor is employed to achieve the desired results, and not infrequently a severe infection may ensue.

It is desirable and in the best interest of the public that the treatment of lesions of this type on the feet be taken care of under the supervision of a physician, for even then a case of lymphangitis may occasionally occur. Moreover, when corn plasters are used by the public on its own initiative there is the added danger that a proper diagnosis has not been made. Although such occurrences are fortunately uncommon, a member of the Council knows of cases of melanocarcinoma starting on the foot. In these cases the patient on first noticing the growth had gone to the drug store and bought a corn plaster. Naturally in such instances the result would be most disastrous.

---

[1] Reports on the examination of ethylene have appeared in THE JOURNAL, Jan. 29, 1927, p. 322; Aug. 6, 1927, p. 451; May 5, 1928, p. 1444.

[2] The following brands have been accepted for inclusion in New and Nonofficial Remedies:
Ethylene-Cheney—The Cheney Chemical Co., Cleveland, Ohio.
Ethylene-C. L. P.—Certified Laboratory Products, Glendale, Calif.
Ethylene for Anesthesia—Puritan Compressed Gas Corporation, Kansas City, Mo. (formerly Kansas City Oxygen Gas Co.).
Lennox Ethylene—Ohio Chemical and Manufacturing Co., Cleveland, Ohio.
Walco Ethylene for Anesthesia—Wall Chemicals, Inc., Detroit, Mich.

Plantar warts are a common condition seen on the feet. If they are not properly diagnosed and treated, there is a decided tendency for these lesions to multiply rapidly, and occasionally anywhere from 25 to 30, up to 100 plantar warts are seen distributed over the bottoms of the feet. Corn plasters have no effect on such lesions, except possibly to soften the top. They do not get rid of the cause and, if anything, tend to spread the disease.

Instances of mycotic infections of the feet accompanied by a proliferation of the epidermal layers, forming more or less keratotic lesions, are frequently seen where corn plasters have been employed—naturally without benefit to the patient.

All types of pathologic conditions on the feet should be seen by the physician and the treatment for these conditions directed by the physician. If this is done, the danger of more serious infections and untoward happenings will be minimized.

The Council considers medicated corn plasters to have the status of a drug the indiscriminate and ill advised use of which by the public should not be encouraged.

---

# Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

## PURITY FINE BREAD

*Manufacturer.*—Purity Baking Company, Pana, Ill.

*Description.*—A white bread made by the sponge dough method.

*Manufacture.*—The sponge dough ingredients, short patent flour of southwest wheat, water, yeast, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, lard, powdered skimmed milk and malt syrup to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper. The factory, equipment and storage rooms are kept in strictly sanitary condition.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 36.5 |
| Ash | 1.9 |
| Fat | 2.8 |
| Protein (N × 6.25) | 10.0 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 48.5 |

*Calories.*—2.6 per gram; 74 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## LONG'S CLIMAX BEST PATENT FLOUR (PHOSPHATE ADDED)

## LONG'S EXTRA FANCY CAKE FLOUR (PHOSPHATE ADDED)

*Manufacturer.*—Climax Roller Mills, Shelbyville, Ky.

*Description.*—A "short patent" soft winter wheat all-purpose family flour admixed with 0.5 per cent calcium acid phosphate; bleached and "matured."

*Manufacture.*—Local soft wheat is cleaned in "separators" to remove imperfect grains, dust and foreign material, is "scoured" in "scouring" machines by being rubbed against a metal screen to remove surface dust, which is drawn off by air suction, and is "tempered" by addition of a definite quantity of water to toughen the bran and prevent it from being pulverized in the milling processes and contaminating the flour. The tempered wheat is coarsely cut and broken only between spirally grooved "break rolls," to facilitate separation of bran from the flour portions. The broken wheat is sifted on screens, a small quantity of flour is taken off, and also some coarse particles "purified wheat middlings" not fine enough for flour but from which the better grades of flour are prepared further on in the milling process. The coarser stock of crushed wheat and bran passes through a second "break rolls," the stock from which is submitted to the same sifting process. Some flour is taken out and also some "purified middlings." The coarse stock again passes to "break rolls" and sifting machines. The reduction and sifting processes are continued until the desired flour separations have been effected. The flour taken off from the sifters goes to special flour bins. The "purified middlings" pass through "purifiers" over silk sieves, through which air currents are drawn to remove bran and chaff particles. The material is ground between smooth steel rolls; the resulting stock is sifted to remove the fine flour. The remaining coarse "middlings" is reground and resifted. The grinding and sifting are continued until all possible flour is obtained. Each time the "mill stock" is sifted, whether it comes from the "break" or "smooth" rolls, a stream of flour is produced. Some of these flour streams are dark in color and others are white and free from specks. The name "patent flour" is applied to that flour made up of those flour streams which are clean in appearance and free from discoloration and apparent specks.

Chosen flour streams are blended for these "short patent" brands of flours; the blend is treated with three-fourths ounce of Beta-chlora per barrel (99.5 per cent chlorine gas and 0.5 per cent nitrosyl chloride—a "maturing" agent to improve baking characteristics) and agitated in a batch mixer with one-fourth ounce of Novadelox per barrel (calcium phosphate and benzoyl peroxide, for bleaching) and 0.5 per cent calcium acid phosphate. The final flour is sacked in new cotton containers only.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 13.0 |
| Ash | 0.7 |
| Fat (ether extraction method) | 1.0 |
| Protein (N × 5.7) | 8.3 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 76.7 |

*Calories.*—3.5 per gram; 99 per ounce.

*Claims of Manufacturer.*—A phosphated "short patent" "all purpose" flour for use in home baking.

## SMACO (400) MALTOSE AND DEXTRINS (Spray Dried)

*Manufacturer.*—S. M. A. Corporation, Cleveland.

*Description.*—Essentially a mixture of approximately equal parts of maltose and dextrins.

*Manufacture.*—A definite quantity of fresh diastatic barley malt and water is admixed with cooked corn flour. The temperature of the mixture is carefully controlled so as to obtain the desired conversion of starch into dextrins and maltose. The conversion is followed analytically by determining the maltose content at regular intervals by means of the copper reduction method. When the conversion has proceeded to that point known to give the desired results, the enzymatic action is stopped by heat. The mixture is filtered to remove any insoluble protein, carbohydrate, etc. The clear filtered liquid is pasteurized and evaporated under reduced pressure to a desired concentration and then spray dried by spraying into a chamber containing hot air currents. The dried powder is packed in hermetically sealed tins.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 3.0 |
| Ash | 0.5 |
| Fat (ether extract) | 0.0 |
| Protein (N × 6.25) | 0.5 |
| Reducing sugars as maltose | 50.0 |
| Dextrins (by difference) | 46.0 |

*Calories.*—3.9 per gram; 111 per ounce.

*Micro-Organisms.*—The cooking of the corn flour, the heat treatment to stop enzymatic action and the pasteurization before spray drying assure the absence of pathogenic organisms.

*Claims of Manufacturer.*—This spray dried maltose and dextrins is especially prepared for use as a carbohydrate supplement for the modification of milk for infant feeding.

## TODDY

### Chocolate and Malt Flavored Food Drink

(Sugar, malt extract, skim milk, cocoa)

*Manufacturer.*—Toddy, Incorporated, Rochester, N. Y.

*Description.*—A powdered mixture of sucrose, malt extract, skim milk and cocoa; packed in carbon dioxide atmosphere in sealed tins.

*Manufacture.*—The ingredients, sucrose, dry malt extract and skim milk, and cocoa, in definite proportions, are bolted through fine screens, mixed in a batch mixer and automatically filled into cans, which are sealed in an atmosphere of carbon dioxide.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 1.0 |
| Ash | 2.9 |
| Fat (ether extract) | 3.3 |
| Protein (noncaffeine and nontheobromine N × 6.25) | 8.5 |
| Theobromine | 2.1 |
| Caffeine | 0.2 |
| Reducing sugars as invert before inversion | 12.5 |
| Reducing sugars as invert after inversion | 64.1 |
| Sucrose (copper reduction method) | 49.1 |
| Crude fiber | 1.5 |
| Total carbohydrates other than crude fiber (by difference) | 80.5 |

*Calories.*—3.9 per gram; 111 per ounce.

*Claims of Manufacturer.*—Especially intended for the preparation of table beverages with milk. Toddy enhances the food value and flavor of milk. Many who dislike plain milk, especially children, invalids, convalescents and the aged, enjoy Toddy-milk beverage. A hot beverage promotes relaxation; "a hot Toddy" before retiring is an aid to restful sleep.

## F. C. B. BRAND GOLDEN SYRUP

*Packer.*—D. B. Scully Syrup Company, Chicago.

*Distributor.*—F. C. Brown Company, Chicago.

*Description.*—A table syrup; a corn syrup flavored with refiners' syrup.

*Manufacture, Analysis, Calories, Claims of Manufacturer.*—See these sections for Banner Blue Corn Syrup with Cane Flavor (The Journal, March 5, 1932, p. 1817).

## BONELESS PEELED PORTOLA SARDINES (In Pure Olive Oil)

*Manufacturer.*—K. Hovden Company, Monterey, Calif.

*Description.*—Cooked, peeled and boneless Pilchard sardines (Clupea caeruleus, blue sardines) packed in olive oil in tins.

*Manufacture.*—Large Pilchard sardines are harvested as described for Portola Sardines (Pilchards) (The Journal, June 4, 1932, p. 1991). Immediately after being landed they are spread on tables, eviscerated and placed in a light brine for fifteen minutes to extract the blood, after which they go over a draper drier for sixty minutes for drying with hot air until the tails become brittle and the skin fairly dry. The skin is taken off; the belly portion is cut with scissors so as to permit the backbone to be pulled out with all the ribs. The fish at this stage are in two halves, which are trimmed down to the right size and placed in cans; olive oil is added. The cans are sealed and processed under the control of the California State Board of Health as to temperature and time.

*Analysis, Calories and Claims of Manufacturer.*—See these sections for Portola Sardines (Pilchards).

## STROEHMANN'S KEW BEE BREAD

*Manufacturer.*—Stroehmann Brothers Company, Williamsport, Pa.

*Description.*—A white bread made by the sponge dough method (method described in The Journal, March 5, 1932, page 817); prepared from patent flour, water, yeast, lard, a yeast food containing ammonium chloride, sodium chloride, potassium bromate and calcium sulphate, salt, sucrose, lard, sweetened condensed skim milk, dextrose, and skim milk.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 37.5 |
| Ash | 0.8 |
| Fat (ether extraction method) | 0.7 |
| Protein (N × 6.25) | 8.8 |
| Crude fiber | 0.2 |
| Carbohydrates other than crude fiber (by difference) | 52.0 |

*Calories.*—2.5 per gram; 71 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## REPORTS OF THE COMMITTEE

The Committee has authorized publication of the following report. Raymond Hertwig, Secretary.

## HOLSUM MILK BREAD SLICED AND UNSLICED NOT ACCEPTABLE

The Miller-Patton Baking Company, Rockford, Ill., submitted to the Committee on Foods a white bread called "Holsum Milk Bread." Prepared from flour, water, skim milk, sugar, salt, yeast, lard, butter, malt syrup, and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 35.1 |
| Ash | 2.0 |
| Fat | 2.6 |
| Protein (N × 6.25) | 10.0 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 50.0 |

*Discussion of Name and Label.*—The name "Milk Bread" defines this bread as conforming to the United States Department of Agriculture definition and standard, which in part stipulates that "Milk bread is the product . . . obtained by baking a leavened and kneaded mixture of flour, salt, yeast and milk or its equivalent (milk solids and water in the proportions normal to milk) . . ." The label statement "Conforms to United States Department of Agriculture Standard" further emphasizes this fact. The name "Milk Bread" for this bread is false and misleading, and especially so in view of the statement of conformity to the government standard, for the reasons that the dry skim milk and butter ingredients of the baking formula are not in sufficient quantities to be equivalent to the milk solids necessary for making the bread a "milk bread" and that the dry skim milk and butter are proportioned so that the mixture is equivalent to skim milk only and not to whole milk. The bread therefore contains skim milk instead of whole milk and the skim milk solids content is much lower than the whole milk solids of a true "milk bread." The label guarantees the bread to contain "milk" and "malt," which is incorrect in that "skim milk" and "malt extract" are ingredients. The name and the two label statements are inappropriate for the bread, are misinformative and are misleading.

The manufacturer when informed of these opinions expressed himself as unwilling to change the name and incorrect label statements in accordance with the Committee's recommendations. This bread therefore cannot be listed among the Committee's accepted foods.

## "PLEZOL POTATO BREAD" NOT ACCEPTABLE

The Frank Baker Bread Company, Lima, Ohio, submitted to the Committee on Foods a white bread called "Plezol Potato Bread." Prepared by the sponge dough method from patent flour, water, yeast, yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, potato ferment containing potatoes, yeast and wheat flour, salt, sugar, lard, sweetened condensed skim milk and malt syrup.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 36.4 |
| Ash | 1.9 |
| Fat | 1.8 |
| Protein (N × 6.25) | 9.9 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 49.8 |

*Discussion of Name.*—The United States Department of Agriculture definition and standard for "white bread" allows for the replacement of not more than 3 per cent of the flour ingredient by some other farinaceous material. The formula submitted for this "Potato Bread" brings it within the terms of the definition for "white bread." The bread has no physical, flavor or nutritional characteristics differing essentially from the usual white bread or suggestive of a bread warranting the name "potato bread." The name is considered inappropriate for the bread, misinformative and misleading.

The manufacturer when informed of this opinion expressed himself as unwilling to change the name in accordance with the Committee's recommendations. This bread therefore cannot be listed among the Committee's "accepted" foods.

SATURDAY, JUNE 18, 1932

## THE SIGNIFICANCE OF TUBERCULIN TESTS

Tuberculin tests have been used in man principally (1) for detecting tuberculous infection in early childhood and for investigating its spread among the children of tuberculous households, (2) as an aid to the physician in the diagnosis of tuberculosis in individual cases, (3) to estimate the prognosis in cases of tuberculosis, and (4) to estimate the distribution of tuberculous infection in communities in different parts of the world. The last mentioned purpose is of fundamental importance in considering the epidemiology of this disease.

The small use that is made of the tuberculin test may be due to misconception of its value in the diagnosis of clinical tuberculosis. Thus it is still commonly believed that the diagnostic applications of the test are confined to early life. This belief is no doubt correct with regard to the positive diagnosis of clinical tuberculosis. A negative reaction excludes this disease with almost equal accuracy at all ages, however, provided the proper method is used and suitable doses are employed. A positive reaction has its chief clinical value in infancy, when, from direct observation, tuberculous infection is more likely than at other ages to be associated with or to progress into active tuberculosis. The earlier the age, the worse the prognosis is. Unfavorable home conditions appear to affect the outlook adversely. The detection of tuberculin sensitivity in infants must, however, be taken only as contributory evidence of the presence of tuberculosis. The mortality among these infants under the present condition of living appears from recent work to be lower than it was formerly believed, indicating that control and arrest of infection are possible. An infant under the age of 2 years with a positive reaction but without symptoms should be kept under observation for some time on account of the possible development of clinical tuberculosis.

A positive reaction in a child, from 2 to 5 years old, with persistent symptoms, should suggest that they are tuberculous in origin. In patients over 5, a positive reaction to a qualitative test does not prove that clinical tuberculosis is present even in a suggestive case. In patients over 5, the positive reaction has its principal value when elicited by quantitative intracutaneous tests with weak solutions of tuberculin. Hence a positive reaction has a limited value in the diagnosis of clinical tuberculosis except in early life. The usefulness of the tuberculin test in diagnosis must therefore come mainly from a negative response, so far as concerns exclusion of the disease. At present the tuberculin test is little used for this purpose because of the erroneous beliefs that a negative test may be obtained in patients with positive evidence of infection, and that either a positive or a negative reaction is of value only in early life. That these beliefs are unwarranted is shown by a recent investigation of Hart,[1] in London. One of the subjects of this investigation was to find the error of a negative intracutaneous reaction in excluding clinical tuberculosis and to determine how this varies with the type and stage of the disease, the age of the patient and the dose of tuberculin employed. A study was made of 1,030 clinically tuberculous patients of all ages, presenting the common types of the disease and every stage from early activity to the moribund state. The reaction of each patient in the series to 0.1 cc. of a 1:1,000 dilution (0.1 mg.) of tuberculin given intracutaneously was ascertained; 766 of these patients were tested with 0.1 cc. of a 1:10,000 dilution (0.01 mg.) and as many as 93 (12 per cent) gave a negative reaction with this dose. Of the 1,030 patients, 38 (3.7 per cent) failed to react to the 1:1,000 dilution. These 38 patients were then tested with 0.1 cc. of a 1:100 dilution (1 mg.) of tuberculin; a positive reaction was obtained in 10 cases, leaving 28 (2.75 per cent) negative. Of these 28 patients, 5 could not be tested further; the remaining 23 were tested with 0.1 cc. of 1:10 tuberculin (10 mg.), 4 of whom were positive and 19 negative. These 19 negative cases were finally tested with undiluted tuberculin 1:1 (10 mg.), which is the maximum intracutaneous dose, with the result that only one more patient gave a positive response. The final and minimal error of the test adjusted for the series was 2.2 per cent. These observations seem to indicate that a negative intracutaneous reaction to a 1:10,000 dilution of tuberculin or to the standard 1:1,000 dilution does not exclude clinical tuberculosis with certainty. A negative test with a 1:10 dilution excludes the disease with greater accuracy, the error of 2.3 per cent being close to the minimal error, 2.2 per cent. For these reasons there is no advantage in using solutions of tuberculin stronger than 1:10 for excluding clinical tuberculosis. Moreover, nonspecific effects of tuberculin become more definite with highly concentrated solutions.

Analysis of the 38 cases out of the 1,030 tested that were negative to a 1:1,000 dilution of tuberculin shows that these fall into certain groups: (1) advanced pulmonary tuberculosis with toxemia; (2) bone or joint tuberculosis with activity; (3) a few nontoxic cases of active pulmonary tuberculosis with positive sputum and a few active cases of bone or joint tuberculosis with definite roentgen evidence of the disease for whose failure to react no reason could be advanced, and (4) a few cases either quiescent or approaching quiescence, all but one of which were also negative to undiluted tuberculin.

---

[1] Hart, P. D.: The Value of Tuberculin Tests in Man, Medical Research Council Special Report Series 164, London, 1932.

As controls for the 1,030 cases of clinical tuberculosis, 751 persons who were clinically nontuberculous were employed. Seventy per cent of the controls aged from 11 to 20 gave positive reactions, and the figures were 95 per cent for the adults of the series. The percentage of the reactions thus rose evenly from birth to manhood. Atypical nonspecific reactions occurred in a few cases of the series investigated by Hart, but their rapid development to a maximum and their rapid subsidence helped to distinguish them from true tuberculin reactions. They usually reached their height during the first twenty-four hours and had completely disappeared by forty-eight hours, when tuberculin reactions are as a rule maximal. The only untoward effects of the intracutaneous tests observed in the series were a few instances of local vesiculation and slight systemic disturbance.

From his study of the epidemiologic applications of the tuberculin test, Hart attempted to show the relative importance of heredity and contagion in determining tuberculous infection. Children from tuberculous households, as shown by Hart's investigation of 118 children of this class, gave a much larger percentage of positive reactions to tuberculin than those whose homes were free of tuberculosis; moreover, the percentage was greater when the tuberculosis was active or open than when it was healed or closed. Children with tuberculous parents living in their homes were more frequently found to react positively than those whose tuberculous relatives visited them occasionally. All these observations seem to be satisfactorily explained by variation in frequency, intimacy and duration of contact without recourse to a belief in hereditary predisposition to infection. The percentage of tuberculin reactions among children exposed in tuberculous households to parents, brothers or sisters with nonpulmonary tuberculosis appears to be no higher than among children in nontuberculous households, nor does it exceed the frequency of tuberculin reactions found among those who have no tuberculous relatives at all. Though the number of cases is small, the results suggest that a positive family history is of importance in determining infection, since it yields a potential intimate source of contagion. Infants separated from their tuberculous parents and placed in healthy families before infection has occurred appear no more likely to acquire the infection in early life than are infants of nontuberculous parents.

## THE RÔLE OF ALCOHOL IN THE ETIOLOGY OF NEPHRITIS

Among the cherished traditions of propagandistic hygiene is the devastating effect of alcohol on the heart, blood vessels and kidneys, a view that still lingers in many medical treatises. Those pathologists who study the remains of an alcoholic clientele have generally failed to find in the wrecks of drunkards anatomic evidence that alcohol is a poison that selects the circulatory system for its attack, but rather the opposite. As for chronic nephritis, there seems to be more tradition than proof indicating that it results from chronic alcoholism. In the older literature, Senator maintained the relationship of alcohol to nephritis, quoting English authors who said that at least three fourths of all cases of chronic nephritis depend on alcoholism. More recently Herxheimer, Löhlein and Bertholet have supported the view of the etiologic importance of alcohol in nephritis. On the other hand, Cohnheim said that although the bodies of most inveterate drunkards exhibit chronic gastritis, meningeal opacity and hepatic lesions, they generally possess large, blood-rich kidneys of good appearance, an observation supported by Fahr, who affirms the lack of evidence of either vascular or renal changes from alcohol, and by Marchand, who noted that the arteries and arterioles of old alcoholic addicts often are splendidly free from sclerotic changes.

Wegelin[1] in Bern has recently made an interesting study of this subject, taking advantage of the fact that the population of this lovely Swiss city shows a remarkably high incidence of cirrhosis of the liver which reaches nearly 10 per cent of recent necropsies, as contrasted with German statistics indicating an incidence of from 1 to 3 per cent. In a series of 106 bodies exhibiting cirrhosis attributable to alcoholism, of which 91 were men and 15 women, he found 12 (11.3 per cent) showing more or less arteriosclerotic nephritis, in only one of which was the condition advanced. In only three bodies was the heart significantly hypertrophied. This amount of cardiorenal disease is certainly not more and apparently is less than would be found in a similar number of bodies of the same age range in which death had occurred from almost any condition. Most of the bodies showed, as described by Cohnheim, large, succulent, blood-rich kidneys, perhaps from functional hypertrophy. On the other hand, in forty-six cases of advanced interstitial nephritis, only five gave a history of excessive use of alcohol. Furthermore, whereas the cases of cirrhosis were chiefly in males (85 per cent), the cases of chronic nephritis in the same necropsy material were nearly equally divided between the sexes (52 per cent males), again indicating the lack of correlation between alcoholism and chronic nephritis.

Our hygiene in the past would seem to have been more a moral hygiene than a scientific one. In a previous generation, a health angle was sought for the promotion of various ascetic doctrines. Our present generation seeks health angles for the continuation of smoking, drinking, chewing gum, and similar pleasures. The pendulum of popular thought prefers the extremes of its travels.

## *HUMAN PARASITOLOGY IN THE NORTHERN STATES*

In certain states that border on the Great Lakes, it is said that there are nine months of winter and three months of poor skiing. On first thought it would seem remarkable that some of the principal contributions to knowledge of human parasitology in the United States should have come from these states. Early progress in parasitic diseases has associated them with the tropics and the subtropics, not with regions where it would seem that microscopic life might find survival difficult. Nevertheless, nearly a quarter of a century ago The Journal began to point out that amebiasis was a disease of northern as well as of southern parts of this country. In a recent issue has appeared an article by Craig [1] in which he awards to Sistrunk an honor long overlooked by the medical profession as a whole; namely, that of reporting in 1911 that, of twenty-five patients seen at the Mayo Clinic who were infected with Endamoeba histolytica, twelve had never resided elsewhere than in northwestern states. Sistrunk had gone to Minnesota from Louisiana. He knew amebiasis, both as a pathologist and as an internist, and his contribution was the start of what might be called propaganda to make physicians conscious that amebiasis is a hazard to health throughout the United States. His studies were followed by those of other investigators in Minnesota, namely, Giffin and Sanford; and ten years later P. W. Brown was still carrying on the work. Now Craig estimates that "the evidence is certainly sufficient to warrant us in stating that 1 per cent of the population, or 1,200,000, are harboring Endamoeba histolytica in this country."

Another problem in parasitology, that of infestation with Diphyllobothrium latum, is predominantly a northern one and has been brought to the fore by residents of the northern part of the Mississippi Valley. Of these, Nickerson, Magath [2] and Essex of Minnesota, and Warthin, Levy, Pierson and Vergeer of Michigan, are prominent. Articles in The Journal have made the fact widely known that Diphyllobothrium latum is a serious matter to the population about fresh water lakes in the north central part of this country. Although the disease apparently was introduced by Finlanders, many cases have been reported among natives of the United States, and Magath has shown that the life cycle of the parasite is completed in this country. The most thorough study of Diphyllobothrium anemia ever made was recently completed by Birkeland, [3] who resided in Minnesota when he did his work. Moreover, studies now under way to determine the incidence of infestation of fish in the winter are being made by Bajkov of the Biological Survey of Canada, who is capturing his material from under the ice.

Thus, physicians and health officers who work north of Chicago have their problems in parasitology as well as those whose homes lie to the south. Although the picture of the white clad parasitologist in his tropical bungalow will persist, it must be supplemented by that of his fur-clad colleague, directing surveys from headquarters almost buried in snow.

## ROENTGEN THERAPY IN POLIOMYELITIS

The use of the roentgen ray as an adjuvant in the treatment of poliomyelitis has been strongly recommended by a number of French clinicians. Other Europeans have doubted its value. In the absence of pertinent experimental evidence for or against such therapy, Lenz and Jungeblut [1] of Columbia University have recently tested the effects of x-rays on experimentally infected monkeys, with a parallel study of in vitro effects on the poliomyelitis virus. Briefly, they conclude that "monkeys suffering from the experimental infection and treated either during the incubation period or with manifest paralytic symptoms furnish no evidence suggesting any benefit from roentgen therapy. . . . Exposure to x-rays failed to destroy or markedly attenuate the virus in vitro." The Columbia University investigators, however, emphasize the obvious differences in virulence and mortality between human poliomyelitis and experimental poliomyelitis in monkeys, and refrain from drawing any final conclusion as to the bearing of their data on human therapy.

## IRON RETENTION DURING GROWTH

There are about 3 Gm. of iron in the body. Although all cells contain a small amount of iron in their nuclei, most of this element is found in the hemoglobin molecule and is therefore found in the blood, muscle, liver, spleen and bone marrow. The iron store in the newborn is not large but there is rapid accumulation of this element in the young under favorable dietary conditions. The ease with which nutritional anemia occurs in young experimental animals on rations poor in iron emphasizes the slender factor of safety provided early in development. It becomes of some importance, therefore, to determine the requirement for iron in the period of rapid accumulation. Leichsenring and Flor [1] have recently reported a study of four children varying in age from 35 to 56 months. On a daily iron intake of 3.25 mg. there was a small positive balance; with 6.5

mg. the retention was more than doubled. Calculated from the excretion on the lower intake, the maintenance requirement was 2.1 mg. daily for the average body weight of 17 Kg., a value almost the same as that currently accepted for adults. The added retention of iron when the intake was increased indicates that growth increases the requirement, and the calculated allowance for this was 3.4 mg. If 50 per cent additional is allowed as a margin of safety, the total daily requirement was 8.23 mg., or, calculated on the basis of food ingested, 0.62 mg. per hundred calories. These data substantiate similar determinations of Rose and her co-workers,[2] according to which a total of 8.5 mg., or 0.76 mg. per hundred calories, is required for a growing child. These studies point to the exaggerated retention of this important inorganic element by young children and emphasize the need for attention to this phase of the food requirement.

## MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 1:30 to 1:35 p. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia chain program has been discontinued for the present.

The program for the week is as follows:

June 20. Flies Are Dangerous.
June 22. Vacation Time is Here.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 11:15 to 11:30 over Station WBBM.

The program for the week is as follows:

June 25. Diets.

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time.

# Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

## ARKANSAS

**Society News.**—At a meeting of the Lawrence County Medical Society, May 10, the speakers were Drs. Cleo C. Ball, Ravenden, on hydrocephalus; Wright W. Hatcher, Imboden, tularemia, and Horace R. McCarroll, Walnut Ridge, episiotomy.——Drs. John L. McGehee, Memphis, and Thomas F. Hudson, Luxora, addressed the Mississippi County Medical Society, May 3, on "Present-Day Mortality Rate of Appendicitis" and "Malaria," respectively.——The Saline County Medical Society was addressed, May 2, by Major James M. Troutt, Hot Springs, on army and navy hospital procedures in dehydration treatment of head injuries, hand infections and diagnosis of appendicitis; Dr. Rolland F. Darnall, Little Rock, discussed "Mental Sickness."——A recent meeting of the Yell-Pope County Medical Society was addressed by Drs. Clarence B. Billingsley, Fort Smith, on "Preventive Pediatric Problems," and John H. Colay, Cleveland, "What Is Wrong with Our Medical Society."

## GEORGIA

**Dr. Elkin Honored.**—Members of the Fulton County Medical Society gave a dinner, April 11, to Dr. William S. Elkin, Atlanta, in celebration of his completion of fifty years in the practice of medicine. The speakers included Drs. Frank K. Boland and William S. Goldsmith, both of Atlanta. Dr. Elkin is a charter member of the Fulton County Medical Society. He has been on the faculty of Emory University School of Medicine for forty-three years and was dean of the school from 1905 to 1925.

**Portrait of Dr. Westmoreland.**—An oil portrait of Dr. John G. Westmoreland, Atlanta, was recently presented to Emory University School of Medicine by Mrs. Julius L. DeGive, Atlanta, granddaughter of the physician. Dr. James L. Campbell, Atlanta, made the presentation address, and Dr. Russell H. Oppenheimer, Atlanta, gave the speech of acceptance on behalf of the university. According to an historical account of Atlanta Medical College, the institution was founded in 1854 "under the energetic leadership of Dr. John G. Westmoreland." This college is now known as Emory University School of Medicine. Dr. Westmoreland was professor of materia medica and therapeutics.

## ILLINOIS

**Poliomyelitis Serum.**—Anticipating an increase in the prevalence of poliomyelitis during the next few months, the state department of public health has collected and is prepared to distribute to physicians on request human convalescent poliomyelitis serum. This serum is available free and can be had at any hour of the day or night. Limited supplies make it impracticable to provide physicians with the serum for anticipated needs, however, so that requests should be confined to immediate requirements. Reported cases up to June 4 this year, the department states, exceed those for the corresponding period in 1931.

**Society News.**—Drs. James P. Simonds and James T. Case, Chicago, conducted a clinical pathologic conference on colon obstructions before the Livingston County Medical Society, May 25, in Pontiac.——The St. Clair County Medical Society was addressed, June 2, by Drs. A. A. Werner on "Ovarian Hormones and Theelin"; Alphonse McMahon, St. Louis, "Structural Changes in Endocrine Disorders," and Charles H. Neilson, St. Louis, "Some Observations of Hyperthyroid States."——Dr. Percy E. Hopkins, Chicago, among others, addressed the Rock Island County Medical Society, Moline, May 11, on "Common Postoperative Complications and Their Treatment."——The Mercer County Medical Society was addressed, May 3, in Aledo, by Drs. Charles P. Blair, Monmouth, on "Fractures of the Neck and Femur," and Elmer G. Senty, Davenport, Iowa, "The Thyroid Problem."——Dr. Ralph M. Carter, Green Bay, Wis., addressed the Macon County Medical Society, Decatur, May 6, on "Fractures of the Femur."

### Chicago

**License Suspended.**—The Illinois State Department of Registration and Education suspended for one year the license of Dr. Joseph Thomas Duffy, June 2. This physician, whose license was issued, Aug. 3, 1925, is now on trial as codefendant with Tilton, the "cancer specialist," for conspiracy to violate the medical practice act.

**Society News.**—The Chicago Society of Allergy was addressed at its May meeting by H. W. Cromwell, Sc.D., and Marjorie D. Moore, Ph.D., on "Rabbit Skin Tests with Pollen Extracts," and O. C. Durham, "Classification and Identification of Hay Fever Pollens."——At the meeting of the Chicago Gynecological Society, June 17, the speakers were Drs. Edward D. Allen on "Irregularity of the Menstrual Function"; Edward L. Cornell and Abraham F. Lash, "A Clinical Study of Abdominal Pregnancy," and William J. Dieckmann and Morris Edward Davis, preliminary report on "Volumetric Determination of Amniotic Fluid with Congo Red."——The Medical Research Club of the University of Illinois was addressed, June 2, by William C. Rose, Ph.D., Urbana, Ill., on "A Search for a New Protein Component Essential for Life."

**In Memory of Dr. Gilmer.**—Two bronze tablets commemorating the work of the late Dr. Thomas L. Gilmer were dedicated, June 7, in Gilmer Hall of the Montgomery Ward Memorial Building, Northwestern University. One tablet records the medical service of the Gilmer family through five generations from 1731 to 1931, the Chicago *Tribune* reports, and the other records the life of Dr. Gilmer. The exercises were conducted by the department of oral surgery, of which Dr. Herbert A. Potts is head. Dr. Gilmer was chairman of the group that founded the Northwestern University Dental School in 1891. He was professor of oral surgery in the dental school for forty years and was dean from 1916 to 1918. He was the author of a book on oral surgery and many papers on dental education, oral surgery and bacteriology, including a classic treatise on jaw fractures. Dr. Gilmer died, Dec. 28, 1931.

---

[2] Rose, Mary S.; Vahlteich, Ella M.; Robb, Elda, and Bloomfield, Emily M., J. Nutrition **3:** 229 (Nov.) 1930.

**Capps Prize Made Annual Award.**—The Joseph A. Capps Prize of $500 will henceforth be awarded annually instead of on alternate years, as originally stipulated by the anonymous donor who established the prize in 1931. This decision was made at the request of the donor because of the general excellence of the papers presented by the twelve contestants for the first award of the prize this year. The original plan was to give the prize one year and to sponsor a lecture the second year. Manuscripts for the second Joseph A. Capps Prize must be submitted to the secretary of the Institute of Medicine of Chicago, 122 South Michigan Avenue, not later than December 31. Competition is open to graduates of Chicago medical schools who have received the degree of doctor of medicine during the year 1930 or thereafter. The prize is awarded for the most meritorious investigation in medicine or in the specialties of medicine. The investigation may be also in the fundamental sciences, provided the work has a definite bearing on some medical problem. The winner of the prize will be expected to present the result of his investigation before the institute at some meeting in 1933, the time to be designated later. The first Joseph A. Capps Prize was awarded to Dr. Warren B. Matthews, assistant resident in surgery at the University of Chicago Clinics, for his paper on "Studies on the Etiology of Gastric and Duodenal Ulcer."

## INDIANA

**County Secretaries Meet.**—Veterans' hospitalization, county medical societies and township poor relief work were included among the topics discussed at the annual conference of secretaries of county medical societies of the Indiana State Medical Association, May 25. Among the speakers were Drs. Franklin S. Crockett, La Fayette, president, state medical society; Joseph H. Weinstein, Terre Haute, president-elect; John C. Burkle, La Fayette; James B. Maple, Sullivan, William H. Kennedy and Chester A. Stayton, both of Indianapolis. The state association gave a dinner to the secretaries in the evening; this session was addressed by Thomas O'Mara, Terre Haute, on "Economics in the Practice of Medicine." Dr. Albert M. Mitchell, Terre Haute, was reelected chairman of the county secretaries' group and Dr. Wilson T. Lawson, Danville, reelected secretary. Dr. Lawson is said to have held his office for fifty years.

**Society News.**—The Carroll County Medical Society was addressed at Flora, May 13, by Drs. Homer H. Wheeler and William F. King, Indianapolis, on "Gastro-Intestinal and Rectal Diseases."——Dr. Oscar E. Nadeau, Chicago, addressed the Wayne-Union Counties Medical Society, May 12, at Richmond, on hematuria.——Among others, Dr. Ralph G. Carothers, Cincinnati, addressed the Eleventh Councilor District Medical Association, May 18, at Marion, on "Fractures of the Lower Part of the Leg and Ankle."——Albert Stump, Indianapolis, addressed the Wabash County Medical Society in North Manchester, June 2, on "Legal Problems and the Care of the Poor."——The Marshall County Medical Society heard an address on "Diagnosis and Treatment of Peptic Ulcer," June 1, in Kokomo, given by Dr. Harry Knott, Plymouth.——At a meeting of the Twelfth District Medical Society and the Northeastern Indiana Academy of Medicine at Kendallville, May 26, Dr. Willis D. Gatch, Indianapolis, spoke on "Heredity as a Factor in Disease," and Dr. Franklin S. Crockett, La Fayette, "Medical Economics."

## IOWA

**Annual Meeting at Twin Lakes.**—The Twin Lakes District Medical Society conducted its tenth annual dry diagnostic clinics at Twin Lakes, Rockwell City, June 16. Dr. Owen H. Wangensteen, professor and head of the department of surgery, University of Minnesota School of Medicine, held a clinic in general surgery; Dr. Robert D. Mussey, professor of obstetrics and gynecology, University of Minnesota Graduate School of Medicine, Rochester, Minn., in obstetrics; Dr. Russell M. Wilder, professor of medicine, Mayo Clinic, Rochester, in medicine, and Dr. Ralph C. Hamill, associate professor of nervous and mental diseases, Northwestern University Medical School, Chicago, in neurology. Speakers on the program included Drs. Rosco G. Leland, director, Bureau of Medical Economics, American Medical Association, Chicago, "Current Trends in Medical Practice," and Ray M. Balyeat, assistant professor of medicine, University of Oklahoma School of Medicine, Oklahoma City, "Allergic Diseases: Diagnosis and Treatment." The Twin Lakes District Medical Society is composed of the county medical societies of Calhoun, Carroll, Greene, Hamilton, Humboldt, Ida, Sac, Kossuth, Pocahontas, Webster and Wright, which are affiliated for graduate clinical instruction.

## KENTUCKY

**Cancer Clinic Opened.**—A free clinic for the diagnosis of cancer, to be conducted for one hour each week, was opened, May 19, at St. Joseph's Infirmary, Louisville, under the direction of Dr. Irvin Abell. All patients will be referred back to their family physicians, who will arrange for their care. No charge will be made for the diagnostic service, regardless of the economic status of the patient. Twenty-four physicians will assist Dr. Abell. This is the second clinic of its kind in Louisville, the first having been opened in January at Norton Memorial Infirmary (The Journal, February 6, p. 486).

**Annual Graduate Course.**—The Kentucky State Medical Association Summer Post-Graduate Course was held at the City Hospital, Louisville, June 6-18. The following speakers, among others, addressed the visiting physicians, Monday, June 6: Drs. John P. Henry, Memphis, Tenn., "Allergy in Theory and Practice"; Victor V. Anderson, New York, "Recent Developments in Psychiatry"; Charles N. Kavanaugh, Lexington, "Tularemia, with Report of 120 Cases" and Marshall G. Seibel, St. Louis, "Tumors of the Islands of Langerhans and Hypoglycemia." Demonstrations in a wide variety of subjects were presented by Louisville physicians during the remainder of the two weeks. Dr. Charles W. Hibbitt was chairman of the committee that arranged the course.

**Public Health Courses.**—The University of Kentucky, Lexington, in cooperation with the state board of health, is offering a number of special courses in public health during the summer session, June 14-July 16. Two courses, one on epidemiology and communicable diseases and one on public health administration, are given only for health officers under the direction of Dr. Allen W. Freeman, professor of public health administration, Johns Hopkins University School of Hygiene and Public Health, Baltimore. Dr. John S. Chambers, professor of hygiene and public health at the university, is conducting a course in health education and health supervision of schools. Other courses offered include personal and community health, public health, maternal and child health, tuberculosis and tuberculosis control and public health nursing. Dr. Arthur T. McCormack, state health officer, Louisville, and other members of the staff of the state board of health will be special lecturers.

**Society News.**—Dr. William R. Davidson, Evansville, Ind., among others, addressed the Christian County Medical Society, Hopkinsville, May 24, on "Treatment of Fractures from the Standpoint of the General Practitioner."——Dr. Charles N. Kavanaugh, Lexington, addressed the Bourbon County Medical Society, Paris, May 19, on "Clinical Considerations of Secondary Anemia."——Drs. Sydney E. Johnson and Aura J. Miller, Louisville, addressed the Harlan County Medical Society, Harlan, May 21, on disorders of the thyroid gland.——Dr. Virgil L. Powell, Paducah, was elected president of the Southwestern Kentucky Medical Association at the recent annual meeting, and Dr. Thomas T. Marshall, Paducah, secretary.——Dr. Robert H. Cowley, Berea, was elected president of the Eye, Ear, Nose and Throat Section of the Kentucky State Medical Society at its twelfth annual meeting in Louisville, May 17. Dr. William Thornwall Davis, Washington, D. C., was the guest of honor at the meeting, reading a paper on treatment of strabismus. The next annual session of the section, which holds meetings separate from those of the state society, will be in Paducah.——The Muldraugh Hill Medical Society was addressed at Elizabethtown, April 14, among others, by Dr. William Allen Pusey, Chicago, on "Our Changing Knowledge of Eczema."

## LOUISIANA

**Quarantine Station Formally Opened.**—The U. S. Quarantine Station at Algiers was formally opened during the recent annual session of the American Medical Association in New Orleans, although it has been in operation since last fall. The Algiers station is one of the largest and most modern quarantine stations in the world; it was constructed from a congressional appropriation of $600,000. It has already begun to function in place of quarantine facilities at three other points in the port, and eventually, it was stated, may replace the present boarding station near the mouth of the Mississippi River if a twenty-four hour boarding service is inaugurated at the new station. This unit comprises nineteen buildings of colonial design, including a hospital, detention house, homes for the officer in charge and other attendants, servants' quarters, and garages. It is said that the first quarantine station was established in Louisiana by Governor W. C. C. Claiborne in 1810 for the purpose of protecting the city against yellow fever. In 1825 this station, which was sixteen miles below New Orleans, was abolished by an act of the legislature, which also abolished the state board of health. A new law in 1855 provided for a station not less than seventy miles below the city. In 1888 it was moved down to the present location of the old station twenty-one miles farther down the river. In 1907, an act of Congress transferred the jurisdiction of this station from the state to the U. S. Health and Marine Hospital Service. Surg. Tully J. Liddell is the officer in charge of the new station.

## MARYLAND

**Portraits of Drs. Lewis and Young.**—Portraits of Dr. Dean DeWitt Lewis, professor of surgery, and Dr. Hugh Hampton Young, clinical professor of urology, Johns Hopkins University School of Medicine, Baltimore, were presented to the university, June 14, at the annual commencement exercises. Both are gifts of colleagues, friends and former students of the physicians. Drs. Lewellys F. Barker, professor emeritus of medicine, and John M. T. Finney, professor of clinical surgery at the school, presented the portraits. Dr. Lewis is President-Elect of the American Medical Association.

**Conference on Juvenile Delinquency.**—Gov. Albert C. Ritchie recently called a conference on juvenile delinquency, which was held under the auspices of the Maryland League of Women Voters in Baltimore, May 17. Dr. James S. Plant of the Essex County (New Jersey) Juvenile Court discussed "Juvenile Delinquency." Other speakers were Drs. John Collinson, Jr., bureau of vital statistics of the state department of health; George H. Preston, commissioner of mental hygiene of Maryland, and Jacob W. Bird, chairman, Montgomery County Juvenile Court Committee, Rockville. Dr. Collinson and Dr. Preston discussed physical and mental examinations of children in the counties, and Dr. Bird, the establishment of a juvenile court in Montgomery County.

## MICHIGAN

**Portrait of Dr. Huber.**—Dr. G. Carl Huber, professor of anatomy, director of the anatomic laboratories and dean of the Graduate School of the University of Michigan, Ann Arbor, was honored, May 16, by the students, friends and colleagues, when a portrait in oil of Dr. Huber was presented to the university. Dr. Frederick G. Novy, director of the Hygienic Laboratory at the university, made the presentation on behalf of the donors.

**Dr. Parker Honored.**—A dinner was given to Dr. Walter R. Parker by his friends and colleagues, May 24, on the occasion of his retirement as professor of ophthalmology in the University of Michigan Medical School, Ann Arbor. Dr. Parker, who has held the position for twenty-seven years, will be succeeded by Dr. George Slocum, his assistant for many years. In 1917 Dr. Parker received the Knapp Medal, which is awarded by the Section on Ophthalmology of the American Medical Association, for a paper on "The Relation of Choked Disk to the Tension of the Eyeball." Dr. Frederick G. Novy presided as toastmaster at the dinner, and Alexander G. Ruthven, Ph.D., president of the university, made the opening remarks. Dr. Parker's retirement is effective, July 1.

**Survey of Medical Facilities.**—A survey of medical service and health agencies will be carried on in Michigan under the direction of a committee of which Dr. W. H. Marshall is chairman, according to the *Journal of the Michigan State Medical Society* for May. It is hoped that through the facts presented the profession may be guided in the adoption of a definite policy concerning the social and economic aspects of medical care. Each county society will appoint a committee on public relations, which will supply certain information and expedite local reports. In the collection of data, detailed schedules will be sent to physicians, hospitals and laboratories. Special studies will cover the economic structure of population, health agencies, industrial service, welfare service, tuberculosis and mental diseases. Miscellaneous studies will be made on workmen's compensation, contract practice, medical society activities, patients discharged from hospitals, and other experiments in solving the economic problem. In the analysis of these data, an effort will be made to determine the distribution of physicians, their professional training, the extent of specialization and the gross cash incomes. Hospital data will be analyzed to indicate, among other things, the distribution and ownership, growth of facilities, type of bed capacities, occupancy and financial status. A somewhat similar analysis will be used for the laboratories. This study of medical facilities is being made in accordance with action taken at the 1931 annual meeting of the Michigan State Medical Society and at a subsequent meeting of the house of delegates. Nathan Sinai, Ph.D., acting director, School of Hygiene and Public Health, University of Michigan Medical School, Ann Arbor, will be the director of the study. Other members of the committee are Drs. Fred A. Baker, Pontiac; Leo G. Christian, Lansing; Bert U. Estabrook, Detroit; Clarence S. Gorsline, Battle Creek, and Frederick C. Warnshuis, Grand Rapids, secretary ex officio.

## MINNESOTA

**State Medical Election.**—Dr. Naboth O. Pearce, Minneapolis, was elected president of the Minnesota State Medical Association at the annual meeting, May 23, to take office, January 1. Dr. Edward A. Meyerding, St. Paul, was reelected secretary.

**Violator of Basic Science Law.**—John Hettwer, 64 years old, Minneapolis, pleaded guilty to a charge of practicing medicine without a license at Hastings, May 2, and was sentenced to nine months in the Dakota County Jail. Hettwer was arrested on the complaint that he had treated a woman for goiter. Hettwer was born in Germany, coming to this country in 1914. He admitted to the court that he practiced a little at Melrose and also at St. Cloud. This is the first prosecution instituted by the medical board in Dakota County since the passage of the Basic Science Law.

## MISSOURI

**Annual Spring Clinics.**—The St. Joseph Clinical Society, St. Joseph, conducted its annual spring clinics, April 20-21, with sessions at the Hotel Robidoux, Missouri Methodist Hospital and St. Joseph's Hospital. The guest speakers included Drs. Vilray P. Blair, St. Louis, on "Repair Surgery"; Edward J. Stieglitz, Chicago, "Nephritis in Pregnancy"; Virgil S. Counseller, Rochester, Minn., "Surgical Significance of the Fascia and Ligaments of the Pelvic Floor and Their Relationship to the Development of Cystocele and Pelvic Relaxation," and Arthur Steindler, Iowa City, Iowa, "Ischemic Contractures of the Forearm." The program consisted of addresses, clinics and round table discussions. Members of the Northwest District Dental Society of Missouri were guests of the clinical society at the banquet.

## NEW YORK

**Smallpox in Plattsburg.**—An outbreak of forty-seven cases of smallpox in Plattsburg and adjacent towns was recently reported in *Health News*. The source of the outbreak was traced to Burlington, Vt., where a Plattsburg family came in contact with a case while on a visit. Four members of the family became ill with smallpox after their return home and the disease spread in Plattsburg and to other villages by easily traced contacts. The health authorities immediately took measures to suppress the epidemic, and a total of 13,819 vaccinations were reported from Clinton County from October 1 to December 31. In Essex County, where some cases were also traced to Plattsburg sources, 5,681 vaccinations were performed. The date of onset of the last reported case was Nov. 24, 1931.

**Dust, Smoke and Gas Nuisances.**—The division of sanitation of the state department of health has recently reported to Governor Roosevelt, after an investigation of several months, the existence of a dust, smoke and gas nuisance from industrial plants on the New Jersey shore, menacing the health and safety of residents of Staten Island. Twenty-six plants in New Jersey and six on Staten Island were investigated. They were principally engaged in the refining and storage of petroleum products, manufacture of chemicals, dyes, paints and fertilizers and the smelting and refining of ores. Smoke, gases, fumes and vapors from many of these contain harmful dusts, acids and compounds of sulphur which when the wind blows toward Staten Island constitute a nuisance or menace to the health of residents of the island. Two plants were said to be principally responsible for the conditions, according to the report, others contributing only infrequently or to so limited an extent that the occurrence could not be considered a nuisance or menace to health. From the weather bureau it was ascertained that the wind blows from the direction of the offending plants about 67 per cent of the time. It was reported that one of these plants was making changes which, when completed, might result in the abatement of the objectionable conditions. Some plants were said not to be contributing to the nuisance at present because of reduced or curtailed operation. It is possible, the report said, that these may expand or resume operations to such an extent as to create a public nuisance on Staten Island.

### New York City

**Salmon Lecturer.**—Dr. William L. Russell, professor of psychiatry, Cornell University Medical College, has been selected to give the Thomas W. Salmon Memorial Lectures for 1933. Dr. Adolf Meyer, Baltimore, recently delivered the first series of these lectures, established in January, 1931, in memory of Dr. Salmon, professor of psychiatry at Columbia University College of Physicians and Surgeons.

**Personal.**—Drs. Lee M. Hurd, professor of laryngology, and John McCoy, clinical professor of laryngology, New York University and Bellevue Hospital, retire from active duty and become emeritus professors at the end of the current year. ——Dr. William Seaman Bainbridge has been appointed an official delegate to the second session of lectures of the International Bureau of Documentation on Military Medicine, to be held at Liége, Belgium, June 23-25.

**Mrs. Biggs' Bequests.**—The late Mrs. Frances R. Biggs, widow of the late Dr. Hermann M. Biggs, bequeathed $100,000 to New York University to increase the funds for the Hermann Michael Biggs professorship of preventive medicine, $35,000 to the Henry Street Settlement for the Hermann and Frances Biggs tuberculosis visiting nurse fund and $1,000 to the New York Tuberculosis and Health Association. A portrait of Dr. Biggs was presented to the Academy of Medicine.

**Social Agencies in New York.**—More than 1,000 social service, health and relief agencies are listed in a new directory issued June 1 by the Charity Organization Society in cooperation with the Welfare Council and twenty other organizations. More than 500 render service to families; 480 are engaged in child welfare; 300 provide health services or health education and 415 are in the field of education, recreation or neighborhood activities, many being engaged in several or all these major activities.

**The Graduate Fortnight at the Academy.**—Tumors, benign and malignant, will be the theme of the 1932 Graduate Fortnight of the New York Academy of Medicine, October 17-28, it is announced. Thirty afternoon clinical meetings and demonstrations have been arranged in eighteen hospitals and ten evening meetings will be held, during which tumor growths will be discussed. Among the speakers will be Drs. W. Gordon M. Byers, Montreal, Que.; Edwin Beer, Charles A. Elsberg and James Ewing, New York; Donald C. Balfour, Rochester, Minn.; Daniel F. Jones, Boston; Dean Lewis, Baltimore, and Francis Carter Wood, New York. Concurrent with the fortnight and for a week afterward there will be an exhibition of anatomic specimens, with lecture demonstrations at regular intervals. The medical profession of the country is invited to attend and participate. There is no charge for attendance, but registration is necessary for the hospital demonstration clinics. Programs and registration blanks may be obtained from the New York Academy of Medicine, 2 East One Hundred and Third Street.

## NORTH DAKOTA

**State Medical Meeting and Election.**—Dr. Jesse W. Bowen, Dickinson, was chosen president-elect of the North Dakota State Medical Association at the annual session in Grand Forks, June 1 and 2. Other officers elected were Drs. Clyde E. Stackhouse, Bismarck, and Archibald D. McCannel, Minot, vice presidents, and Albert W. Skelsey, Fargo, secretary, reelected. Dr. Paul H. Burton, Fargo, was inducted into the presidency. Valley City was selected for the 1933 meeting place. Guest speakers listed on the program included the following:

Dr. Roscoe C. Webb, Minneapolis, "Drainage in Appendicitis."

Dr. Harry F. Bayard, Minneapolis, "Etiology, Course and Treatment of Anal Pruritus."

Dr. Russell M. Wilder, Rochester, Minn., "Ten Years' Experience with Insulin."

Dr. Owen H. Wangensteen, Minneapolis, "Recognition and Treatment of Pulmonary Suppuration."

Dr. Henry W. Cook, Minneapolis, "Relationship of Clinical and Insurance Medicine."

Dr. Hugo O. Altnow, Minneapolis, "Diseases of the Blood."

Dr. Arthur W. Ide, St. Paul, "Internal Injuries Involving Internal Organs."

Dr. Charles B. Wright, Minneapolis, "Veterans' Legislation."

The North Dakota Academy of Ophthalmology and Otolaryngology met in conjunction with the association with Drs. Axel Oftedal, Fargo, and Henry E. Binger, St. Paul, as the speakers, on mastoiditis.

## OHIO

**Student Prizes at Western Reserve.**—Norman Reider, Canton, Ohio, student in the department of anatomy, Western Reserve University School of Medicine, Cleveland, has been awarded the Dr. Herbert S. Steuer Prize for Work in Anatomy for investigations on the evolution of the primate colon and the relation to the human colon. The senior prize in obstetrics, the gift of Dr. Edwin C. Garvin, was awarded to Miss Elizabeth S. Hutchinson, Cleveland, as the member of her class who showed the best theoretical and practical knowledge of the subject.

**Society News.**—Drs. Maurice I. Miller, Troy, and Herbert R. Pearson, West Milton, addressed the Miami County Medical Society, at West Milton, May 13, on toxemias of pregnancy and traumatic surgery, respectively.——Drs. Myron Metzenbaum and Raymond C. McKay, Cleveland, addressed the Stark County Medical Society at Alliance, May 25, on "Nasal Reconstruction and Reconstructive Surgery" and "Results of Compression Methods of Treatment of Pulmonary Tuberculosis," respectively.——The Summit County Medical Society, in association with the Summit County Dental Society and the Medical Bureau of Akron, is publishing a twenty-four-page bulletin called the *Medical Arts Journal*.——Drs. Charles Anderson Aldrich, Winnetka, Ill., and Henry J. Gerstenberger addressed the Academy of Medicine of Cleveland, May 20, on "Science and Art in Child Nourishment" and "Radiant Energy—Its Use in General Practice," respectively. ——Dr. Justin M. Waugh, Cleveland, gave an address before the Portage County Medical Society, Ravenna, May 5, on "Diseases of the Esophagus."——George R. Effler, attorney, addressed the Toledo Academy of Medicine, June 3, on "Doctors and Lawsuits."——The Academy of Medicine of Cincinnati and the Cincinnati Dental Society have established joint headquarters in the Union Central Life Building. In addition to an assembly hall which the societies have heretofore used for meetings, there will be offices, a lounge and library.—— Drs. Don C. Hughes and John M. Firmin addressed the Hancock County Medical Society, Findlay, June 2, on Addison's disease and treatment of hemorrhoids, respectively.—— Dr. George E. McKean, Detroit, addressed the Summit County Medical Society, Akron, June 7, on pneumonia.

## PENNSYLVANIA

**Society News.**—Dr. Charles C. Wolferth, Philadelphia, addressed the Delaware County Medical Society at the Springhaven Country Club, June 9, on "Angina Pectoris and Coronary Occlusion."——Dr. George Wagoner, Philadelphia, was the speaker before the Cambria County Medical Society, Johnstown, June 9, on "Evidence of Disease as Seen in the Skeletal Remains of Antiquity."——Drs. Otto C. Gaub and Ernest W. Willetts, Pittsburgh, addressed the Washington County Medical Society, June 8, on "The Abdomen as a Diagnostic Problem" and "Diagnosis and Treatment of Anemia," respectively.

### Philadelphia

**Hospital News.**—A five-story addition, to be known as the Benjamin Rush Building, was opened at the Philadelphia Children's Hospital, June 1. The building is named for a descendant of Dr. Benjamin Rush, Philadelphia physician and signer of the Declaration of Independence. It gives the hospital a capacity of 200 beds and adds to the dispensary and outpatient departments.——A research laboratory for pathology and bacteriology, equipped at a cost of $25,000, has been opened at St. Joseph's Hospital.

**New Building for Jewish Hospital.**—Mrs. Anna Esther Fridenberg has presented to the Jewish Hospital $400,000 in cash for the erection, equipment and partial upkeep of a surgical ward building. The gift was a legacy left to Mrs. Fridenberg by the will of her brother, M. S. Fridenberg, who requested that she use the money to build a memorial to members of the Fridenberg family. Plans for the Fridenberg Memorial Surgical Building will provide for fifty-six ward beds, four operating rooms and other necessary facilities. It is expected that construction will begin soon.

**University News.**—Dr. Madge Thurlow Macklin, of the University of Western Ontario Medical School, London, addressed the staff of the Cancer Research Laboratories, University of Pennsylvania Graduate School of Medicine, May 31, on "The Rôle of Inheritance in Human Neoplasms and Its Diagnostic Significance."——George Barton Cutten, Ph.D., president of Colgate University, Hamilton, N. Y., was the guest speaker at the commencement of Jefferson Medical College, June 3; his subject, "A Layman's Advice to Doctors." June 2 was Alumni Day, which was celebrated with clinics at the Jefferson Hospital, followed by the annual dinner.

## TEXAS

**After Thirty Years' Service.**—Dr. Alonzo Garwood, who has been health officer of New Braunfels more than thirty years, recently resigned on account of ill health. During Dr. Garwood's term of office he has served the city under seven administrations of mayors.

**Society News.**—Drs. Wayne T. Robinson and Sim Driver spoke at a meeting of the Dallas County Medical Society, June 9, on "The Aschheim-Zondek Test for Pregnancy" and "The Maggot Treatment of Osteomyelitis," respectively. A symposium on neurosyphilis will be presented at the meeting, June 23, with the following speakers: Drs. Truman C. Terrell, Fort Worth; Guy F. Witt and Arthur G. Schoch, Dallas. ——Dr. William Hodges McKnight addressed the Tarrant County Medical Society, Fort Worth, May 17, on "Symbiotic Infection of Abdominal Operative Wounds."

## WEST VIRGINIA

**Society News.**—Dr. Fred W. Rankin, Rochester, Minn., addressed the Ohio County Medical Society, Wheeling, May 20, on "Surgical Treatment of Cancer of the Large Bowel."——Dr. Chauncey B. Wright addressed the Cabell County Medical Society, Huntington, May 12, on the cause of pain and rigidity in appendicitis.——Dr. Harry E. Mock, Chicago, was the speaker at a joint meeting of the Monongalia, Harrison and Marion county medical societies at Morgantown, May 25, on "Back Injuries."——Drs. William W. Strange and Raymond M. Sloan, Huntington, addressed the Kanawha County Medical Society, Charleston, May 11, on "Surgery of the Sympathetics" and "Ketogenic Diet in the Treatment of Epilepsy," respectively. ——Dr. Alexander J. Burkholder, Layland, among others, addressed the Fayette County Medical Society, Oak Hill, May 11, on undulant fever.

**State Medical Meeting at Parkersburg.**—The sixty-fifth annual meeting of the West Virginia State Medical Association will be held in Parkersburg, June 20-23, under the presidency of Dr. Albert H. Hoge, Bluefield. Guest speakers will be:

Dr. Mont R. Reid, Cincinnati, "Treatment of Thyroid Intoxication."
Dr. Bernard H. Nichols, Cleveland, "Excretion Urography."
Dr. Hugh S Cumming, Washington, D. C., "Public Health Service, with Special Reference to Milk Sanitation."
Dr. Elmer B. Freeman, Baltimore, "Practical Value of Special Diagnosis Methods in Study of Digestive Diseases."
Dr. Albert Graeme Mitchell, Cincinnati, "Practice of Preventive Pediatrics."
Dr. Samuel Goodwin Gant, New York, "Plea for Perineal Versus Other Procedures in Rectal Cancer Extirpation."
Dr. Waitman F. Zinn, Baltimore, "Cancer of the Larynx."
Dr. Victor W. Fischbach, Cincinnati, "Study of Sinus Disease in Children."
Dr. Jacob A. Bargen, Rochester, Minn., "Differential Diagnosis of Types of Colitis and Their Treatment."
Dr. Henry H. Kessler, Newark, N. J., "Estimation of Permanent Disabilities in Industrial Accidents."
Dr. Dean Lewis, Baltimore, "Differential Diagnosis of Bone Lesions."

Dr. Hoge will deliver his presidential address Tuesday evening, June 21, entitled "A Medical Retrospect." The annual banquet will be held Wednesday evening, with Dr. Gant as the speaker, and the annual golf tournament will be run off Monday, June 20.

## WISCONSIN

**Dinner in Honor of Dr. Bardeen.**—The medical faculty of the University of Wisconsin will give a dinner at the Memorial Union, Madison, June 20, in honor of Dr. Charles Russell Bardeen, marking his twenty-fifth anniversary as dean of the medical school. Dr. Bardeen, a native of Michigan, was graduated in medicine from Johns Hopkins University School of Medicine in 1897 after having taken an academic degree at Harvard. He remained at Johns Hopkins as a member of the teaching staff until 1904, when he came to Wisconsin as professor of anatomy.

## GENERAL

**Yellow Fever Volunteer in Hospital.**—John H. Andrus, one of the army enlisted men who allowed themselves to be bitten by mosquitoes infected with yellow fever in the famous experiments by the Yellow Fever Commission in 1900, has recently entered Walter Reed General Hospital, Washington, D. C., to undergo treatment for paralysis. Mr. Andrus, who is advertising manager for a manufacturing firm in Camden, N. J., is said to have suffered from arthritis for eighteen years. With other members of the group, he was awarded a Congressional Medal and a pension of $125 a month in 1929 in recognition of his service.

**Dr. Long Awarded Trudeau Medal.**—Dr. Esmond R. Long, Chicago, was awarded the Trudeau Medal by the National Tuberculosis Association, June 6, at its annual meeting in Colorado Springs, Colo. The medal is awarded each year "for outstanding service to the tuberculosis movement," the Chicago *Tribune* reports. Dr. Long, professor of pathology, Graduate School of Medicine of the Division of Biological Sciences, University of Chicago, recently resigned his professorship, which he had held since 1928, to go to Phipps Institute of the University of Pennsylvania, Philadelphia, as director of laboratories. He received his bachelor's degree, doctor of philosophy and medical degree, all from the University of Chicago.

**Association for Study of Feebleminded.**—The fifty-sixth annual session of the American Association for the Study of the Feebleminded was held, May 26-29, in Philadelphia, under the presidency of Dr. Harvey M. Watkins, Polk, Pa. Among the speakers were Edgar A. Doll, Ph.D., Vineland, N. J., on "Psychological Aspects of the Birth-Injured Mentally Deficient"; Dr. Leon Pierce Clark, New York, "Psychoanalytic Interpretation of Mental Arrest," and Dr. Charles S. Woodall, Belmont, Mass., "Offspring of Feebleminded and Mentally Subnormal Mothers." Dr. Howard W. Potter, New York, was installed as president, and Dr. Ransom A. Greene, Waverley, Mass., was chosen president-elect. Dr. Groves B. Smith, Godfrey, Ill., is secretary.

**Credentials Stolen.**—Dr. John H. Hrabik, Murphysboro, Ill., writes that about May 1 his office was entered by a morphine addict, who took, among other things, his army discharge papers, army compensation certificate and a pass book on the First National Bank of Murphysboro. Since that time numerous forged checks have arrived at the bank from points in Indiana, Kankakee and East St. Louis, as well as letters from physicians who received forged checks. In all cases, the person has been posing as a World War veteran who had purchased a farm in the vicinity, and using Dr. Hrabik's credentials as identification. The checks, which have ranged from $2 to $90, amount to about $400. Should this man be apprehended, please notify the sheriff of Jackson County, Murphysboro.

**Milwaukee Wins Health Conservation Contest.**—Milwaukee won first place among cities of more than 500,000 population in the annual health conservation contest sponsored by the United States Chamber of Commerce in cooperation with the American Public Health Association. Winners in other population groups were: Rochester, N. Y., 250,000 to 500,000; New Haven, Conn., 100,000-250,000; Evanston, Ill., 50,000-100,000; Brookline, Mass., 20,000-50,000, and La Salle, Ill., 20,000. There was an increase in enrolment of more than 27 per cent, the chamber of commerce reported. Although the requirements were higher in the 1931 contest than in 1930, more than 70 per cent of the cities that competed in both years made higher scores in 1931, it was said. Each city was awarded a bronze plaque at a ceremony at the annual meeting of the United States Chamber of Commerce in San Francisco, May 17.

**Display of Public Health Equipment.**—The first display of equipment, materials, methods and services for the furtherance of public health ever to be held on the Pacific Coast has just been announced. This will be the Los Angeles County Public Health Exposition, which will be conducted in the buildings of the International Industrial Expositions, Limited, August 12-18, under the auspices of the Los Angeles County Tuberculosis and Health Association. Many other associations interested in public health have arranged to participate in this enterprise. There will be exhibits by schools, health departments, recreation departments, chambers of commerce, and other similar organizations. Products and equipment of recognized standard used in disease prevention and health building will be shown and all types of appliances and equipment, products and materials, and methods and services pertaining to health and sanitation will be displayed. A board of directors and an advisory committee have been appointed. The technical committee appointed by the board of directors will pass on applications for exhibiting space.

**Medical Bills in Congress.**—*Changes in Status:* Government competition with private enterprise has been the subject of investigation during the week by a committee of the House, appointed pursuant to H. Res. 235. Representative Shannon, Missouri, is chairman of the committee. H. R. 10238 has been reported to the Senate, without amendment, creating a reimbursable fund to be used for special medical and surgical work among the Indians of the Fort Peck Indian Reservation, Montana. H. R. 11267, the economy bill, has passed the Senate, with amendments. As reported to the Senate, the bill contained several provisions dealing with compensation and hospitalization of veterans, among which was one proposing, in effect, to deny free hospitalization for nonservice disabilities to those veterans financially able to pay for treatment. The Senate, however, eliminated from the bill all provisions relating to veterans except one section creating a joint congressional committee to conduct a thorough investigation of the operation of the laws and regulations relating to the relief of veterans and to report to Congress not later than Jan. 1, 1933. H. R. 12448 has passed the House, amending the Disabled Emergency Officers' Retirement Act. Under this bill, an emergency officer whose disability is only *presumptively* of service origin will not be entitled to retirement under the act. The bill is now pending before the Senate Committee on Military Affairs. H. R. 11897, the War Department appropriation bill, has passed the Senate, with amendments. As passed by the House, this bill proposed to reduce the number of officers in the army from 12,000 to 10,000, substantially reducing the number of officers in the medical corps. It proposed, too, the discontinuance of the training of physicians and dentists for military service through the Reserve Officers Training Corps. The Senate struck out these provisions, but whether this action is effective will depend on the result of conferences between conferees on the part of the Senate and of the House.

**Society News.**—The American Physiotherapy Association, an organization of technicians, will hold its annual meeting in Milwaukee, June 27-30.——Dr. William deB. MacNider, Chapel Hill, N. C., was elected president of the American Society for Pharmacology and Experimental Therapeutics at its annual session, April 30; Alfred N. Richards, Ph.D., Philadelphia, vice president, and Dr. Velyien E. Henderson, Toronto, Canada, secretary, reelected. The next annual meeting of the association will be held at Cincinnati, April 10, 1933.——At the annual session of the American Pediatric Society, May 28, Dr. Oscar M. Schloss, New York, was made president, and Dr. Hugh McCulloch, St. Louis, reelected secretary. The society will meet, May 1-3, 1933, in Washington, D. C.——The officers of the American Otological Society for the ensuing year are Drs. George L. Tobey, Jr., Boston, president; John R. Page, New York, vice president, and Thomas J. Harris, New York, reelected secretary. The next annual session of the society will be held at Washington, D. C., May 2-3, 1933.——Dr. Joseph C. Beck, Chicago, was named president of the American Laryngological, Rhinological and Otological Society, May 25, and Dr. Robert L. Loughran, New York, reelected secretary. The society will meet in Chicago in 1933.——At the annual meeting of the American Laryngological Association, Dr. George Fetterolf, Philadelphia, was elected president, and Dr. George M. Coates, Philadelphia, secretary. The next session of the society will be held in Washington, D. C., May 2-4, 1933.——The thirteenth annual conference of the American Federation of Organizations for the Hard of Hearing will be held in San Francisco, June 20-23, under the presidency of Dr. Austin A. Hayden, Chicago. Speakers at the scientific session and their subjects will be Drs. Hayden, "Willing Ears"; Isaac H. Jones, Los Angeles, "Hearing Aids"; Moritz Weber, San Francisco, "Research in Deafness," and Mrs. Annette Abbott Adams, San Francisco, legal aspects of this handicap.——Dr. George P. Muller, Philadelphia, was elected president of the American Association for Thoracic Surgery at the recent annual meeting in Ann Arbor, Mich. The 1933 session will be held in Washington, D. C.——Dr. Richmond McKinney, Memphis, was elected president of the American Bronchoscopic Society at the annual meeting in Atlantic City, May 21.

## HAWAII

**Territorial Election.**—Dr. Grover A. Batten, Honolulu, was elected president of the Hawaii Territorial Medical Association at its annual meeting in Honolulu, April 23-25. Other officers of the association are Drs. Wah K. Chang, Honolulu; Archie Orenstein, Hilo; Lawrence L. Patterson, Kapaa, and William T. Dunn, Lahaina, vice presidents; and Dr. Lyle G. Phillips, Honolulu, secretary, reelected. The program of the association included as speakers Dr. Frank C. Spencer, Honolulu, on "Trichomonas Vaginalis Vaginitis"; Dr. Newton E. Wayson, Honolulu, and Theodore Rhea, "Leprosy: Some Observations on Its Epidemiology in Hawaii"; Drs. Guy C. Milnor and Eric A. Fennel, Honolulu, "Placental Diseases"; Douglas B. Bell, "Primary Pneumococcus Peritonitis"; Adolph G. C. Schnack, Honolulu, "Flatulence"; Randolph L. McCalla, Lanai City, "Effect of Hydration on the Action of Insulin"; Stewart E. Doolittle, Honolulu, "Tuberculosis as a Family Disease"; Grover A. Batten, Honolulu, "Gastric and Duodenal Ulcer: Some Observations Concerning Surgical Mortality"; Joseph W. Lam, Honolulu, "Methods of Contraception"; Clarence W. Trexler, Honolulu, "Modern Treatment of Ozena"; Nils P. Larsen, Honolulu, "Response of the Arterial Tree to Exercise"; Edward S. Goodhue, Hoolehua, "The Marching Years"; Arthur W. Duryea, Honolulu, "Lobar Pneumonia Survey"; Major Albert Bowen, Honolulu, "Use and Value of Postmortem Radiographs," and Dr. Ralph E. Cloward, Honolulu, presented a case report. Dr. Joseph E. Strode, Honolulu, delivered the presidential address on "The Progress of Medicine in Hawaii."

## CANADA

**Dr. Penfield to Head Neurologic Institute.**—With the announcement of a grant of $1,232,652 from the Rockefeller Foundation to McGill University, Montreal, for the establishment of a neurologic institute, plans for the development of a neurologic center at the school were disclosed. The grant will provide for the construction of a new building, specially equipped for research in neurology, neurosurgery and the physiology and pathology of the nervous system. More than $150,000 has been pledged by friends of the university and members of the governing board. Dr. Wilder G. Penfield, professor and head of the department of neurology at McGill, has been selected to direct the institute. Dr. Penfield was born in Spokane, Wash.; he is a Rhodes scholar and a graduate of Johns Hopkins University School of Medicine. His associates will include Drs. Colin K. Russel and Frederick H. MacKay, clinical professors of neurology, and William V. Cone, assistant professor of neurologic surgery, also a native of the United States. The new building will be erected on a site opposite the present neurologic laboratories in the Royal Victoria Hospital building. The institute will be connected with the hospital and the pathologic building by an underground tunnel. Tentative arrangements provide for the erection of a seven story building to contain wards for public, semiprivate and private rooms, operating rooms, research laboratories, offices, and a few rooms for resident graduate students.

## FOREIGN

**Personal.**—Sir Aldo Castellani of the London School of Tropical Medicine and Hygiene is one of four recipients of the Mussolini Prize of 50,000 lire (about $2,500) for special distinction during the past year, according to *Science*.

**Cholera in Shanghai.**—One hundred and ninety cases cholera have been reported in Shanghai, according to the Cl cago *Tribune*, June 7. In an effort to check the epidemic, t report said, the authorities have inoculated 135,000 persons.

**Victor Horsley Memorial Lecture.**—Dr. Edgar Dougla Adrian, Foulerton research professor of the Royal Society a Cambridge University, will give the triennial Victor Horsley Memorial Lecture, July 20, on "Visceral Sense Organs." This lectureship was established in 1920 to commemorate the services of Sir Victor Horsley to science and the British Empire. Its trustees are the presidents of the Royal Society, the Royal College of Surgeons of England and the British Medical Association, the senior physician to the National Hospital, Queen Square, the senior surgeon to University College Hospital and Mr. Stanley G. Robinson, son-in-law of Sir Victor Horsley. Dr. Adrian recently lectured in Philadelphia (The Journal, Nov. 21, 1931, p. 1547) and other cities in the United States.

**Society News.**—The Société de Neurologie held its annual international reunion, May 31-June 1, in Paris. Epilepsy was the subject selected for study, with Drs. Foerster, Breslau; Pagniez, Paris; Abadie, Bordeaux, and Crouzon, Paris, as the speakers. Research carried on under the auspices of the Déjérine Foundation was announced at this meeting: Dr. Baudouin spoke on "Experimental Hyperpnea"; Drs. Mr. and Mrs. Sorrel-Dejerine, "Pott's Paraplegia," and Dr. Cornil, Marseille, "Anatomic Classification of the Marrow and It- Covering." The Charcot Prize winner, Dr. Alajouanine, spok on "Anterior Subacute Poliomyelitis."——The twelfth session of the "Medical Days of Brussels" will be held, June 25-28, under the presidency of Prof. Fernard Heger. Practical demonstrations will be given in the hospitals, and the theoretical lectures will be presented by medical authorities from various countries of Europe. Dr. René Beckers, 141, rue Belliard, Bruxelles, is secretary-general.——American physicians who expect to attend the second International Congress of Oto-Rhino-Laryngology in Madrid, Spain, September 27-30, are requested to send their notification blanks without delay to Dr. Alberto Fumagallo, secretary-general of the congress, at Madrid. The official ship for American delegates will leave New York, September 17, and proceed direct to Vigo, Spain. Information may be obtained from Marcel Colin, 8 Investment Building, Washington, D. C.

### A Criticism of Diet

A committee of authorities on diet, consisting of Sir F. Gowland Hopkins, Prof. E. P. Cathcart, Prof. Edward Mellanby and Prof. V. H. Mottram, appointed to advise the minister of health on the practical application of modern advances in the knowledge of nutrition, has submitted a memorandum on the criticism and improvement of diets. The committee considers that the needs of the adult man are 3,000 calories a day and of the adult woman, 2,500. For children under the age of 1 year the daily need is 600 calories; from 1 to 2 years, 900; 2 to 3 years, 1,200; 3 to 6 years, 1,500; 6 to 8 years, 1,800; 8 to 10 years, 2,100; 10 to 12 years, 2,400; girls 14 years or over, 2,500; boys 14 years or over, 3,000. In temperate climates the range for protein is from 10 to 15 per cent of the total calories, for fat 20 to 35, and for carbohydrate 50 to 70. If the amounts of protein and fat fall much below 80 and 50 Gm., respectively, a day, or the percentage of calories derived from carbohydrate rises much above 66, the diet is in need of improvement.

A second criterion is the supply of first class protein. Some proteins replace a greater amount of protein lost in the body by wear and tear than others and are also more adequate for purposes of growth. These are termed first class proteins and (for practical dietetics) are found only in animal products, such as cheese, eggs, fish, meat and milk. The amount of first class protein necessary per man daily is 37 Gm. Most middle class diets contain about 55 Gm. but working class diets frequently fall below the standard.

The third and fourth criteria are mineral matter and vitamins. Unfortunately there are as yet no quantitative data of the amount of the different vitamins essential. However, the foods that are useful in supplying mineral matter are useful in supplying vitamins. For example, liver and egg yolk, which are good sources of iron, supply also vitamin A, and egg yolk also supplies vitamin D; fish liver and roe, which supply iodine, also supply vitamins A and D; milk and cheese, which supply calcium, supply vitamin A. The chief essential mineral elements are calcium, phosphorus, iodine and iron. There is evidence that too little calcium, iodine and iron are frequently contained in the diet. Calcium is found in cheese, egg yolk, milk, bran and green vegetables; phosphorus, in cheese, egg yolk, milk, bran and oatmeal; iodine, in sea foods (fish, shellfish and dulse) and a few leafy vegetables (watercress, beet leaves, onions); iron, in egg yolk, meat, liver, oatmeal and green vegetables.

The essential vitamins are found as follows: Vitamin A occurs in liver, carrots, butter, milk, cheese, most animal fats (not lard), yellow fruits and vegetables and green vegetables. Vitamin B consists of many fractions, but there is little evidence that it or its essential components are absent to any important degree from any but the worst balanced diets. Moreover, if the diet is satisfactory as regards vitamins A, C and D, it is probably complete as regards vitamin B. Vitamin C is found in fresh foods and is the only vitamin which suffers much in domestic cooking, so that cooked vegetables and fruit should not be relied on. Vitamin D is found in fat fish (especially in fish liver oils), fish roe, egg yolk, summer milk butter and green vegetables.

Of the mineral matter, calcium is most likely to be deficient in this country and possibly iodine in certain hilly and mountainous districts. Of the vitamins, the most likely to be missing is D, followed by A and then C. It will be seen that if a diet contains milk and dairy products generally, fish, eggs and fresh salad vegetables there is little need to criticize it as regards its mineral and vitamin content. There are no quantitative data as regards the need for vitamins, but probably if the diet contains one pint of milk daily, plenty of cheese, one orange or one tomato or a helping of raw salad, and if an ounce of butter (or vitaminized margarine) is given, and if some sort of fat fish, such as herring, appears in the winter menu once a week (or, in default, half a teaspoonful of cod liver oil is taken), the mineral and vitamin content of the diet is satisfactory.

### Prescriptions in Cipher

Attention has been called in the press to the practice of giving patients a prescription in cipher, to which a certain pharmacist holds the key. The practice is new and probably confined to a few physicians. In a press interview Dr. Cox, medical secretary of the British Medical Association, has described it as "an abominable practice. . . . The use of codes of this kind may give rise to a suspicion that some kind of financial arrangement has been arrived at between the pharmacist and the consultant. There is also the implication that some secret remedy is being used, which is grossly unprofessional. A patient should be able to produce prescriptions to any other doctor he consults later, so that the treatment he is having is known." On the other hand, the system has been defended on the ground that it preserves the utmost secrecy. The patient does not know what drug he is taking and the danger of his becoming an addict is eliminated. If he should in any way detect the drug he cannot present the prescription to another pharmacist and obtain it. For medical reasons it is sometimes desirable that a patient should not know what drug he is taking.

### British Health Resorts

The financial depression has given rise to a movement "to keep the money in the country" by using British health resorts instead of the popular continental ones. The British Health Resorts Association has been formed with the support of many leading physicians. The last of three conferences held by it has been held at Bournemouth, on the south coast. Sir Thomas Oliver, who presided, said that few islands had such an imposing coast line and such attractive scenery as our own, the number and variety of the coast resorts being unsurpassed. Dr. William Byam, lecturer on tropical diseases at St. George's Hospital Medical School, said that he had endeavored to keep patients in this country but had met too many failures. He gave the following record of reasons for not staying in England, in the order of frequency: (1) climate, (2) English standard of cooking, (3) unfashionableness of our resorts, (4) need for more complete change of scene and occupation, (5) lack of amusements, (6) the ban on gambling, (7) greater cost of a holiday here, and (8) absence of facilities for treatment. Dr. R. Fortescue Fox declared that in the matter of organization we were behind other nations. On the continent, health resorts enjoyed state support, and admirable handbooks on them were distributed in England. Dr. Manson-Bahr said that diet in British health resorts was the thing that bothered him. There seemed to be no one to supervise the diet in a case of, say, sprue, in which treatment was almost entirely dietetic.

### The Unhygienic Condition of Merchant Ships

At the Congress of the Royal Institution of Public Health, which has been held in Belfast, Sir Thomas Oliver, emeritus professor of medicine in the University of Belfast, strongly criticized the sanitary condition of merchant ships. He pointed out that in 1910 the death rate of seamen from pulmonary tuberculosis was almost double that of most other occupations; that valvular disease of the heart was double, pneumonia 80 per cent above the average, and accident four times the basic figure. In 1921-1923 the general mortality of seamen was 76.8 per cent above the average and for pulmonary tuberculosis 35.5 per cent in excess. The high death rate from pulmonary disease showed, among other things, the inadequacy of the sleeping accommodations on board ship. He considered that the condition on British ships was worse than on those of other nations. Of the ships inspected in the port of Manchester in 1926, 30.5 per cent of the British ships were found to be insanitary, 18.9 per cent of the Norwegian, and 17.2 per cent of the American.

### Bats as Carriers of Rabies

The legislature of Trinidad has voted $1,000 as an honorarium to Dr. Pawan, who proved that bats were the carriers in the recent outbreak of rabies in the colony. Mr. Grier, speaking for the government, declared that the amount hardly covered Dr. Pawan's expenses, but it was an acknowledgment of his great work. Dr. Pawan is the Trinidad government bacteriologist. The disease that he has traced to bats baffled investigators for a time, who ascribed the deaths caused by it to "a virus of rabies of a hitherto unknown type." In a report to the government last November, the suggestion was made that bats were the carriers. This was confirmed by Dr. Pawan, who found lesions typical of rabies in the brain of a bat.

### Research on Microbic Polymorphism

The question of microbic polymorphism continues to have great interest for biologists, and particularly the study of filtrable types of micro-organisms. The optical laboratory of Professor Fabry has succeeded, it seems, in manufacturing such powerful apparatus that the investigator is enabled to observe the presence of frankly visible granulations, by means of a special form of illumination, in cultures filtered through the most dense candles under heavy pressure. These researches will soon be published. Mr. Hauduroy has described an evolutional cycle of Bacterium typhosum. Under the action of the d'Herelle bacteriophage, the bacilli of typhoid and paratyphoid are capable of assuming invisible filtrable forms. These are found in some typhoid patients, either in the blood at the beginning of the infection or in the stools at the termination of the disease. They provoke certain septicemias, in which it appears that the normal form of the bacillus is not found. Mr. Hauduroy thinks also that contaminated water contains usually only filtrable forms and that the bacillus itself is not found. These discoveries justify therefore the following hypothesis: The healthy individual becomes infected through the ingestion of invisible filtrable forms of Bacterium typhosum. These develop gradually in the organism, taking on eventually the bacterial forms; then, when the disease terminates, these bacterial forms are again broken up by the bacteriophage, or in some other manner, and scattered about through nature under their first invisible filtrable form. This theory leads to a conclusion that has a great significance for public health; namely, that drinking water in which the usual microbiologic researches have been unable to show the presence of a typhoid or paratyphoid bacillus may nevertheless be capable, under certain conditions, of producing a typhoid infection. Research of the same nature has been undertaken by Dr. Vaudremer, who for years has been patiently studying the polymorphism of the tubercle bacillus and its filtrable forms. He even succeeded in securing an attenuated form that gives excellent results in the treatment of latent tuberculosis of the joints, the glands and the bones, as has been mentioned in previous letters. At present, he is engaged in studies on the bacillus of leprosy and he has secured some interesting results. In collaboration with Mr. Sézary and Mlle. Brun, by cultivating successively fragments of cutaneous leprosy and of leprous spleen in a filtered extract of Aspergillus fumigatus, in Martin's bouillon, ordinary potato bouillon and glycerinated potato bouillon, Mr. Vaudremer secured pseudomeningococcal gram-positive forms, short and granular cyanophil bacilli; long, flexuose and granular cyanophil bacilli, and finally acid-resistant forms. This evolution covered a period of about two years. Fragments of lepromas were ground up in aspergillar fluid. This fluid filtered through candle $L^3$ did not produce cultures during the first nine months; but, from that time on, pseudomeningococcal forms appeared in the potato bouillon and developed into acid-resistant forms. Vaudremer and Sézary think that the organisms that develop from these cultures are forms of the Hansen bacillus and that this bacillus, similar to many others, may present itself in the form of elements that pass through an $L^3$ candle.

### Radium in the Treatment of Uterine Cancer

In response to the communication of Professor Jean-Louis Faure, addressed to the Academy of Medicine, pertaining to the encouraging results that he had secured from total abdominal hysterectomy in the treatment of uterine cancer, Mr. Regaud, director of the Institut du radium, presented a paper, at the following meeting of the academy, in which he submitted the statistics of his institute on the subject. He took account only of the cases treated at least five years previously. From 1922 to 1926, 429 cases of all degrees of extension were treated, in which 142 recoveries (33 per cent) were secured, which are judged now after the lapse of at least five years. The authors counted among the failures eleven women who died from intercurrent disease and seven women (1.6 per cent) whose whereabouts is unknown, but who were in good health at last accounts, but before the lapse of the five-year period. Of all the patients judged cured at the end of the fifth year, in only four has a recurrence since been noted. Of the cases of the first degree in which the neoplasm appeared confined to the cervix, twenty-nine were treated by radium alone, twenty-three of whom (79 per cent) recovered. There were no deaths. The surgical statistics recently published by Jean-Louis Faure appear more brilliant because they included only a selection of the best cases of the first degree. But if one adopts a common definition of the lesions, one finds only 70 per cent of recoveries. The cases of the second degree—that is to say, at the limit of operability—treated at the Institut du radium numbered 121 and furnished 50 recoveries (41 per cent, as compared with 23 per cent at the gynecologic clinic). The cases of the third degree, with extensive invasion of the parametrium, which are not amenable to surgical treatment, furnished 27 per cent of recoveries of five years duration at the Institut du radium. It is apparent from these facts, according to Mr. Regaud, that, even in the better cases, the radiotherapeutic methods give results superior to those secured with the Wertheim operation. Although equal from the standpoint of technical perfection, this operation has therefore only rare indications.

### Refusal of Surgical Aid Following an Occupational Accident

The Société de médecine légale recently devoted two sessions to the discussion of the question whether the refusal, by a person suffering an occupational accident, to submit to an operation, decided on by the physician—a refusal that would increase his degree of invalidity—was legally of such a nature as to justify a reduction in the compensation to be paid by his employer. The question was brought up first by a communication of Dr. Leclercq of Lille with reference to the radical treatment of hernia. Mr. Leclercq emphasized that French law was not very clear on this point and that the various courts of the country had rendered quite contradictory decisions in the matter. He therefore asked the Société du médecine légale to render an opinion that would serve to guide the courts in the future. His personal opinion is that a radical intervention in hernia, even in a healthy person and although performed under local anesthesia, cannot be considered devoid of risk to life. That was also the opinion of Dr. Duvoir, court medicolegalist. He recalled the opinion formulated by the Academy of Medicine during the war, when the question of the right of a wounded person to refuse an operation was put before it by the minister. He cited also the opinion of Professor Boudin, who has treated this subject in a recent work, in which he points out that the question of consent to operations has created a conflict with the new social laws. It is unquestionably true that "the patient is master of his own body." But the social laws pertaining to aid and civil responsibility in common law bring in a third party, namely, the general public, which is responsible for the cost of treatment and for the degree and length of invalidity. The obligation imposed by the law on the employer to indemnify the victim of an occupational accident entails an obligation on the workman to submit to the treatment prescribed by medical science; but the workman retains nevertheless the right to refuse to undergo an operation. It is the duty of the courts to determine the motives for his refusal. If the refusal is not justified by the gravity of the operation or the uncertainty of the results, the judge is entitled to reduce, or even to suppress, the daily indemnity, and the court may reduce the percentage of disability to that which would still be present if the operation had been performed. After the consolidation, the condition of the victim is regarded as final and no operation can be imposed by the employer, nor, on the other hand, can an operation then be demanded by the workman. Mr. Mouchet, in the case of hernia, holds that one can only strongly advise the patient to submit to the operation, calling his attention to the fact that it is to his interest in order to avoid possible strangulation later, but an operation cannot be forced on him if he refuses, for it cannot be denied that there are risks involved. The question was then raised as to the right of the surgeon to impose on a wounded person an operation that may save his life, when the patient is unconscious and cannot be consulted in the matter. The same question arises with reference to wounded mental patients. If the case is not urgent, it is better to seek authorization from the family of the mental patient, the latter being regarded as a child before the law. The conclusion of the discussion was that, in spite of the grave risk of herniary strangulation to which the patient is exposed who refuses an intervention, one cannot impose an operation for the radical treatment of hernia (1) because the operation cannot be declared absolutely without danger, and (2) because one cannot affirm that the operation will assure a definitive recovery.

### Celebration of Centenary of Alfred Fournier

The centenary of the French syphilologist Alfred Fournier (1832-1914) was celebrated by ceremonies that lasted a week. They began, May 9, with a meeting of the Conférence internationale contre la syphilis. Among the foreigners attending were Jadassohn of Breslau, Ehlers of Copenhagen, and a number of Belgian, Italian and Spanish syphilologists. The celebration of the centenary was to have been held, May 12, at the Sorbonne, with the attendance of the president of the republic. In the interval, the president was assassinated and his funeral was held on the day set for the holding of the ceremony. The celebration was therefore transferred to the more modest quarters of the museum of the Hôpital St. Louis. A number of speakers described the work of Fournier, which began with the discovery of syphilitic chancre and soft chancre and ended with the announcement of the syphilitic origin of tabes and of dementia paralytica, and by his works on heredosyphilis. On this occasion, the enlarged Hôpital St. Louis and the new institute termed the Alfred Fournier Institute were dedicated. This institute contains laboratories for serologic and experimental researches, the control of medicaments and an antivenereal dispensary. This institute will be the headquarters of the Ligue française contre le péril vénérien and of the Société de prophylaxie sanitaire et morale. On account of the national mourning for the president, all the planned festivities were abandoned.

### Congress of the German Roentgen Society

Under the chairmanship of Professor Grebe, director of the Röntgenforschungs-Institut of the University of Bonn, the Deutsche Röntgengesellschaft held its congress in Dresden, April 3-5. More than seventy addresses and communications were presented. In spite of the economic depression, and the large number of congresses that have followed one another in quick succession, about 600 German and foreign participants appeared, and the congress offered a good survey of the present status of roentgenology. The first day was devoted to technical, the second to therapeutic, and the third to diagnostic addresses.

Behnken and Brasch, both of Berlin, dealt with roentgen rays of the highest penetrative power. The production of high tensions is easy for technicians, but more difficult is the production of correspondingly resistant tubes. With a special type of generator, roentgen rays can be produced that will penetrate 20 cm. of lead. The speaker mentioned a tube that, supplied with 2,400,000 volts, furnishes alpha particles and cathode rays of great penetrative power. The roentgen rays produced by it correspond approximately to the gamma rays of radium. With a system capable of supplying 7,000,000 volts, which will soon be available, roentgen rays of much greater penetrative power can be produced. It is hoped that with their aid the breaking up of atoms can be successfully carried out.

H. Franke of Hamburg and Mühlmann of Stettin discussed the use of roentgen paper for photographs, which was followed by a spirited general discussion of the subject. The quality of these papers, which have been on the market since 1923, has been improved. The relatively low price has been retained and the noninflammability has been preserved. Nevertheless, the sharpness of outline of the pictures is considerably less than in the film. They are, therefore, usable only when fine details need not be brought out.

On the day devoted to therapy, G. A. Rost, dermatologist of Freiburg, discussed the biologic bases of roentgen therapy in dermatology. He considered the action on the blood capillaries, the differences in sensitiveness, formation of pigment, physicochemical changes, remote injuries, and action in inflammations (no direct antibacterial action). The basis of indications has remained about the same in recent years, with the exception that indirect irradiation is more accentuated.

Schreus of Düsseldorf spoke on dosimetry, and methods of surface therapy. The Sabouraud tablet is useful with careful measurement of hardness and the observation of certain rules. The Sabouraud dosage should be expressed in r units on the basis of graduated curves. As the maximal doses for irradiation up to a 3 mm. aluminum half-value shield, one can figure 600 r, or with a 20 per cent safety factor, 500 r; for softer rays than with a 0.5 mm. half-value shield, only 400 r. The speaker discussed also the measurement of hardness, the distribution of doses in high voltage therapy and protective devices. Hintze of Berlin reported on 800 skin cancers irradiated in the Bier clinic. The grenz rays, which were severely criticized by many, found several defenders. Schubert of Berlin reported on experiences gained thus far with the treatment of carcinoma by means of extremely hard roentgen rays. By distributing the total dosage over fourteen days, the effect was increased so that a fairly good skin reaction developed. Haupt of Bonn gave statistics on cancer of the neck of the uterus, for the years 1915-1926, treated by operation and irradiation combined. Cures extending over five years in all operative cases were 42 per cent; absolute five-year recovery, 29.7 per cent. Dietel of Heidelberg described the present method of irradiating cancer of the neck of the uterus, at the Universitäts-Frauenklinik, Heidelberg. The best results were secured in one-stage high radium dosage with a definite technic. Large primary tumors are extirpated. For the parametrium a supplementary roentgen dose is necessary. Philipp of Berlin called attention to peculiar bone disorders in patients with uterine carcinoma subjected to roentgen irradiation.

A discussion took place on injury to the offspring by roentgen irradiation. As the Deutsche Gesellschaft für Vererbungswissenschaft had issued a warning, which, in the opinion of leading physicians, went too far, a corresponding counterdeclaration was given at the joint meeting of the Bayerische Gesellschaft für Geburtshilfe und Gynäkologie and the Bayerische Gesellschaft fur Röntgenologie und Radiologie, and was published in the special medical journals. Further information based on more comprehensive hereditobiologic researches and on joint researches and investigations of students of hereditary transmission and of physicians is expected shortly. Several speakers reported on the ultra short wave therapy, its physical and biologic bases and its technic. Good results were observed at the Universitäts-Frauenklinik in Berlin.

In the field of roentgen diagnosis, Albert Fraenkel of Heidelberg gave a paper on the limitations of roentgenology for the diagnosis of beginning pulmonary tuberculosis from the clinical and roentgenologic points of view. In judging some roentgenograms, one must be reserved in one's statements. Examinations at certain intervals are necessary. Unfortunately there have not been a sufficient number of necropsies covering the primary stage in early childhood and the "early case," in the adult. The roentgenogram furnishes the only diagnostic control of a possible reinfection, in the form of a number of round foci. The tuberculous focus disappears slowly and never entirely. The roentgen observation is superior to the physical but must not be exaggerated. In open tuberculosis the roentgen manifestations may be negative; that is, there are concealed cavities back of the dome of the diaphragm and back of the heart shadow, which come into view only on deep inspiration or with diagonal exposure. In a lung that appears sound and intact roentgenologically, there may be an arrested tuberculous process. Pleural adhesions and indurations may remain concealed in the roentgenogram. The roentgenologist must be thoroughly informed in regard to the patient. Wurm of Heidelberg discussed the limitations of roentgenology for the diagnosis of beginning pulmonary tuberculosis. He considered the anatomicopathologic points of view in judging the genesis and extension of specific lung foci and brought them into harmony with the roentgen manifestations. Only in 7 per cent of the cases does pulmonary tuberculosis begin with tuberculosis of the apex, which is readily diagnosed by clinical and roentgenologic means. The speaker does not consider that a "retrograde lymphogenous propagation" has been proved. The roentgenologic distinction of specific and nonspecific indurations is scarcely possible.

Kaestle of Munich presented a paper on pneumonoconioses. Extensive researches in industrial plants, chiefly with reference to sandstone, porcelain, cement, shell-lime, granite, cotton, hemp and polishings of grinding mills showed that a high percentage of silicon oxide is essential for the development of lung changes. In mines the external conditions that give rise to injuries are much more even and uniform than in factories; the individual predisposition also is important. With the same roentgen and clinical manifestations, the subjective complaints are widely different. Silicosis with degeneration and cavity formation may be free from tuberculosis. In involvements of the apex a sharp distinction between pneumonoconiosis and tuberculosis may be impossible. As a rule, however, one can recognize or suspect a silicosis preceding the tuberculosis or following the tuberculosis. Kaestle never saw a carcinoma resulting from dust irritation. Böhme of Bochum described the pneumonoconioses in miners of the Ruhr district. He had seen also carcinoma.

A lively discussion arose on the subject of hernia hiatus oesophagi. Adam of Berlin observed in forty healthy subjects that on deep inspiration a stenosis appears at the lower end of the esophagus, which leads to the formation of a sac-like diverticulum just a little higher up. As against these functional pseudohernias, Knothe of Berlin, Schatzki of Leipzig and Berg of Dortmund described the pathologic picture of true hernia of the hiatus oesophageus. H. U. Albrecht of Frankfort showed by comparison of roentgen manifestations and corresponding pathologic preparations of parts of the digestive tract to how great an extent the roentgenogram constitutes a necropsy in vivo. Gutzeit of Breslau spoke on the anatomic and functional diagnosis of gastro-enteritis with the aid of the roentgenogram. The appearance of the mucosa does not usually avail much. But one finds the sinus ventriculi dilated, the bulbus duodeni usually flaccid, the passage through the small intestine accelerated, and an increase of fluid in the small intestine and the colon. G. Velde of Greifswald in six out of forty-two cases of pernicious anemia found gastric polyps with the aid of the roentgenogram.

Kienböck of Vienna was chosen chairman of the society for 1933, and Bremen will be the place of meeting.

### Medical Motion Pictures

The origins of cinematography go back to the laboratory of the physiologist, for the first experiments with instantaneous photography were undertaken to study the various kinds of movements occurring in man and animals. Since that time the film has become of great importance for medical science. It should be used for medical instruction much more than it has been. That is the demand of the surgeon Prof. A. W. Fischer and the psychiatrist Dr. E. Herz, who, writing in the *Deutsche medizinische Wochenschrift*, discuss the status of medical cinematography. Fischer demands more particularly the practical development of films for the imparting of instruction in surgery, while Herz demands a systematic collection of films dealing with the subject of research on movements in general in man. Only a central institute could accomplish these tasks. The Kaiserin-Friedrich-Haus in Berlin, which promotes postgraduate medical education, has already begun to prepare a catalogue of all existing medical films, but that is only a beginning. How the film should be used for diagnostic purposes in nervous and mental diseases is shown by Herz in his application of the method to the study of motion; for it will be recalled that it has become possible by means of films to distinguish pathologic from normal movements. Numerous other problems have been elaborated in the same manner. The restless movements of certain mental patients were studied in their peculiar form by means of a careful analysis of the film. The film may be used also as an aid in establishing the degree of disability, since the manifestations of attacks are given a fixed form in the film and serve then later as undeniable fact-finding material in rendering a decision in a given case. Thus the film takes on the character of evidence in various procedures. But the film has possibly its greatest value in the presentation of manifestations of mental patients in classroom instruction. A knowledge of disturbances of motion cannot be properly imparted without a "film textbook."

### Decline in the Sales of Beverage Brandy

The Reichsmonopolverwaltung (administration of federal monopoly), which controls the sale of brandy in Germany, has published a report of sales for the period from January 1 to March 31, 1932, according to which the sales of beverage brandy for that period amounted to only 46,726 hectoliters, as compared with 87,764 hectoliters for the corresponding period of last year. It is evident, therefore, that the consumption of beverage brandy has almost been brought to a complete standstill. The extent of this reduced consumption and the resulting decline in the revenues of the *reich* from the brandy monopoly will stand out more clearly if the recent sales' figures are compared with those of the corresponding quarter of the fiscal year 1928-1929 (before the last tax increase), during which, as compared with 46,726 hectoliters, 223,873 hectoliters was sold.

### Meeting of the Medicosurgical Society

The first meeting of the Società medico-chirurgiche delle Tre Venezie was held recently at Cornegliano on the Piave, under the chairmanship of Professor Cagnetto. The chief topic on the program was the treatment of gastric and duodenal ulcers, the medical side being presented by Professor Tramontini and the surgical side by Professor Oliani.

Professor Tramontini discussed theories as to the etiology of gastroduodenal ulcer: that of Virchow and Hagem; that of Lembe and Riegel, and the views of von Bergmann. He concluded that the problem is still unsolved.

With regard to the treatment of chronic ulcer, the speaker emphasized the importance of medicodietetic treatment as recommended by different authors and stressed the need of cooperation between physicians and surgeons.

Professor Oliani discussed the problems with regard to the surgical treatment of gastric and duodenal ulcers based on his experience in 1,200 cases. He advocates radical treatment; namely, gastroduodenal resection. If done with precise technic, resection does not present greater risks than conservative surgical methods.

In the general discussion, Fasiani brought out that, in the surgical treatment of gastroduodenal ulcer, one must distinguish between gastric ulcer and duodenal ulcer, in which latter he had observed good results from a simple gastro-enterostomy.

Pieri reported good results obtained in some cases of juxtacardiac ulcer with bilateral subdiaphragmatic vagotomy. Such treatment was applied with good results also in cases of postoperative peptic ulcer and recurring gastric ulcer following resection.

Popotoschnig, on the basis of experience in 294 cases of gastroduodenal resection for ulcer, considered this the most rational intervention in these types and emphasized the need that all cases of acute conditions of the abdomen be turned over to the surgeon as early as possible, since only in that manner, without loss of time over diagnostic discussion, could the operative results, in perforated ulcers as well, be improved. Arlotta, on the basis of experience in seventy-five cases, in which various operations were performed, declared himself in favor of resection.

Manu stated that he was an advocate of the Leube diet. Excluding ulcer complications that require a surgical intervention, the speaker recommended conservative medicodietetic treatment except in cases in which medical measures are not tolerated or in which, for social reasons, the patient requires an operation. The next session will be held at Venice, the chief topic on the program being "Pathology and Clinical Aspects of Extrahepatic Biliary Tracts."

### Lenses Applied to the Cornea

Professor Gualdi presented recently to the Accademia medico-fisica of Florence a special type of lens in the form of very thin capsules of glass, which are applied directly to the eyeball and in immediate contact with it, and are practically invisible. The speaker explained the technic of the application and announced the excellent results that he had secured from their first systematic use in Italy, at the Clinica oculistica in Florence, for the correction of myopia, hypermetropia and astigmatism, with many advantages over the use of spectacles; among others, an increase in visual acuity. The speaker recommended the use of this type of lens in many professions and social activities in which spectacles cannot well be worn.

### Acute Anterior Poliomyelitis

At a meeting of the Accademia medico-chirurgica del Piceno, presided over by Prof. L. Cappelli, acute anterior poliomyelitis was discussed. Dr. Monti Guarnieri discussed the etiology and concluded that the causative agent is a filtrable virus and that the most common port of entry is the nasopharynx. The virus may be carried with impunity in the nasopharyngeal cavity for six or seven months and then be transferred from one individual to another.

He referred to some of the notable epidemics (that of 1916 in the United States and that of 1924 in Italy), and stated that children under 5 years of age are most subject to the disease, although an occasional case is found among adults. He described the symptoms and spoke of the forms of treatment, which, if applied early, may be helpful: convalescents' serum and Pettit's serum.

Professor Montanari explained the therapeutic action of various forms of physical therapy. He said that importance attaches at present to electrotherapy, local hot hydrotherapy, diathermy, massage, and active and passive gymnastics. He expressed himself, however, in a somewhat reserved manner as to the utility of radiotherapy. He emphasized the need of hospitalization for patients with acute anterior poliomyelitis in pediatric departments connected with the hospitals of the chief towns in the provinces.

Dr. Bartoli spoke on sequels of poliomyelitis. He emphasized that paramount attention should be given the possible beginning of deformations of the trunk and of the lower limbs. Greater cooperation between medical specialists is needed in order to be able to treat in the most complete manner and with the most satisfactory results infantile paralysis in all its manifestations, so as to prevent deformities.

Professor Montanari presented a resolution in which the academy recommended that hospitals of the chief provincial towns be provided with a pediatric department in which all persons might have an opportunity of securing physicotherapeutic and orthopedic care, in order that the consequences of this disease may be warded off.

The next session of the Academy will be held in Jesi, the chief topic on the program being "The Treatment of Diabetes."

### The Treatment of Cerebral Tumors

Prof. G. Ayala presented to the Accademia dei fisiocritici di Siena a communication on the treatment of cerebral tumors. He explained a method that he had followed in many cases in which blindness was threatened and in which any sort of radical operative intervention would have been hazardous. Under such circumstances the physician must endeavor to combat the symptoms of intracranial hypertension. To that end the speaker proceeded to puncture the cerebral ventricles. He extracted ventricular fluid in varying amounts depending on the presence or otherwise of an obstructive hydrocephalus. He employed an intraventricular insufflation of sterile air, in small quantities when he did not wish to use ventriculography. He followed up the ventricular puncture with subtemporal or suboccipital decompressive craniotomy and, finally, subjected the patient to deep irradiation in three periods: one immediately after the craniotomy, one after from forty to fifty days, and one after the lapse of a year (two erythema doses for each cycle of irradiation, divided into from eight to sixteen sittings). The speaker presented one patient with a tumor of the posterior cranial fossa, who entered his clinic in a grave condition. The patient stood excellently the ventricular puncture, the craniotomy and the first series of deep irradiations. At present the patient is so much improved that only careful examination reveals a slight cerebellar syndrome, whereas the symptoms of cranial hypertension are reduced to a papillary edema, but considerably diminished as compared with what it was at first. The course of events alone will tell whether it will be necessary to intervene locally for the surgical removal of the tumor.

### The Inaugural Lecture of Professor Castellani

Prof. Sir Aldo Castellani, senator, delivered an inaugural address in connection with the opening of the new Clinica delle malattie tropicali, of the University of Rome, and dealt with the subject "Tropical Medicine from Ancient Times Down to the Present." Tropical medicine, Professor Castellani stated, is possibly the most ancient branch of scientific medicine, since the most ancient civilizations began in tropical or subtropical countries. In Egypt, evidence of specialization in the fifth century is found. Following the Roman and the Arabian periods of medicine, the school of Salerno remained all through the Middle Ages the most famous center of medical instruction. Against leprosy and the plague, tropical diseases *par excellence,* the Middle Ages were obliged to adopt defensive measures. In the modern era, Portuguese and Spanish physicians began researches on tropical medicine. Fracastoro and Atanasio Kircher prepared the way for the discoveries in bacteriology and parasitology, confirmed later by the use of the microscope. The speaker declared that if there is any field of medicine in which therapy can score brilliant successes, tropical medicine is that field.

## MADRID

*(From Our Regular Correspondent)*

April 16, 1932.

### International Congress of Surgery

The Sociedad Internacional de Cirugía recently held at Madrid its ninth congress, which delegates from several foreign countries attended. This is the first international scientific reunion held since Spain was made a republic. The inaugural session in the Palacio del Sando was attended by Mr. Alcalá Zamora, president of the republic, who made an eloquent speech. Mr. Zamora gave a reception and banquet at the royal palace to the congressmen and their families. The civic authorities also fêted the visitors in typical Spanish fashion. During the congress the topics discussed dealt with problems on the progress of surgical anesthesia, intraspinal tumors, suppuration of nontuberculous lung, and surgery of the esophagus. When the scientific sessions were over, the visitors made a trip through the most artistic cities of Spain. They were impressed by the good will existing everywhere and by the cooperation that all classes showed the government and scientific authorities.

#### TREATMENT OF SUPPURATION OF NONTUBERCULOUS LUNG

The first subject discussed during the congress was the treatment of suppuration of the nontuberculous lung. The following are the articles discussed: Dr. Howard Lilienthal of New York distinguished the following forms of suppuration of nontuberculous lung: (1) more or less gangrenous bronchiogenic abscesses of the lung; (2) metastatic pulmonary abscesses (secondary to infection caused by an infarct); (3) suppurative bronchopneumonia; (4) gangrenous bronchopneumonia (a variety of suppurative bronchopneumonia); (5) interstitial pneumonitis; (6) suppurative lymphangitis (a variety of interstitial pneumonitis); (7) suppurative bronchiectasis. Dr. Lilienthal emphasized the importance of the presence of anaerobic bacteria in the mouth or in the pharynx for the development of pulmonary suppuration and the etiologic significance of operations in the mouth, which sometimes cause the unexpected appearance of gangrenous pulmonary suppurations. With regard to treatment, one may distinguish pulmonary abscesses and suppurative bronchiectasis.

#### PULMONARY ABSCESSES

The presence of pulmonary abscess is determined by: (1) the history of the patient, which is of great importance; (2) fever; (3) cough, which may not appear until the interstitial abscess has reached a large bronchus; (4) fetor; (5) the physical signs, which may not appear until an advanced period; (6) the roentgen examination, which should be made in all cases and to which the speaker devoted a large part of his article; (7) bronchoscopy, which has a diagnostic value, especially to determine the seat of the suppurative focus; (8) the puncture, which should not be made until everything is ready for the performance of a radical intervention if it is indicated. The puncture has been followed in many cases by serious and fatal accidents. Not all types of abscesses should be treated by drainage. Abscesses of the lung should be distinguished as progressive, stationary or regressive, and not as putrid or nonputrid, chronic or acute. The rapidity of the development of the abscess and the degree of virulence of the infection determine the advisability to perform the operation. Not all acute abscesses of the lung should be operated on, although their evolution should be watched closely so that the operation, if indicated, is made at the proper time. As a rule, operations demanded by acute abscess of the lung are not so urgent as those demanded by such other conditions as strangulated hernia or acute appendicitis. However, it is preferable to evacuate interstitial suppurative collections rather than to take the risk of their rupture into a bronchus as the result of delay. As to local treatment, bronchoscopic aspirations cannot be made continuously, and the continuation of artificial pneumothorax is indicated only when marked improvement occurs during the first week following its institution. The technic for evacuation by thoracotomy is determined by the site of the abscess. However, the principles of the operation are the same in all cases and may be summarized as follows: 1. The patient's head should be at a lower level than that of his hip bones in order to prevent cerebral air embolism. 2. Local anesthesia is preferable; the anesthesia should not suppress the cough reflex, as then there is danger of aspirating infected matter in the other lung. 3. The evacuation should be made through the most direct route without entering the pleural cavity. 4. The abscess should be opened first at its inferior border. 5. Skill should prevent the appearance of any hemorrhage, which may endanger the operation. 6. The packing should not be so tight that it displaces the mediastinum. 7. The thorax should not be enclosed in a dressing. 8. The formation of flaps should be avoided, because they make further examinations of the operative field more difficult. The rib, which covers the abscess, is resected; the parietal pleura is opened, and then the operative field is isolated from the rest of the pleural cavity, by surrounding the abscess with gauze and a covering of rubber, both of which have the aim to promote the formation of pleural adhesions. Some days later, when adhesions have formed and the abscess is isolated, it is entered with a cannula attached to an aspiratory syringe. If pus comes through the cannula into the syringe, a pair of closed scissors is introduced into the cavity of the abscess, then opened and withdrawn. The surgeon's finger may now explore the abscess cavity and a gauze drain, previously moistened with antigangrenous serum, may be inserted. The drainage tube may be removed in about one month. Sometimes, after the drain has been removed, the wound heals and then reopens; this has no importance, because the wound will later heal definitely.

#### SUPPURATIVE BRONCHIECTASIS

The information gathered from bronchoscopy and that from the roentgen examination are complementary. The patient is in good general condition, and no characteristic symptoms may be discovered, with the exception that he has clubbed fingers, fetid breath and expectoration of foul smelling mucopurulent matter, the amount of which does not bear any relation to the lesion in the bronchi. The remission of symptoms is frequent. The treatment frequently used is daily postural evacuation of the bronchus. Phrenicotomy, artificial pneumothorax and the bronchoscopic treatment are useless. There are palliative operations. Thoracic drainage through a bronchial stoma, although not followed by recovery, causes a diminution of the pus expectorated and makes the fetor disappear. The technic of the operation is similar to that for the evacuation of abscess of the lung, previously described. The speaker, after reviewing other methods to obliterate the bronchiectatic area, described his own method as follows: A space is formed between the parietal pleura and the ribs, by introducing a gauze packing, which is increased in size during the first few days, and then a caoutchouc ball, until the apex of the lung has been forced back and a space formed the size of a large orange. Thoracoplasty, according to Sauerbruch's method, may be resorted to when one of the lungs is normal. A marked improvement may thus be obtained, and even the clubbed fingers may disappear. Among the radical operations one may resort to is lobectomy, preceded a few days by thoracotomy. The pathologic lobe of the lung should be isolated. Its pedicle is compressed and ligated in several places. The ligatures should be long enough to come out of the posterior angle of the operative wound. Hemostasis should be carefully made. To avoid the formation of putrid empyema and bronchial fistulas, Lilienthal touches, first with gauze and then with iodine tincture, the visceral and parietal pleuras of the normal lobes which limit the one on which lobectomy is going to be performed. Then the thorax is closed. A few days later the exudate which forms after thoracotomy is evacuated and lobectomy may be performed two weeks later. The speaker's statistics include forty resections with twenty-five fatal results (62.5 per cent). In twenty-seven cases the entire lobe or its pathologic portion was resected; death occurred in seventeen cases (63 per cent). In thirteen cases an adjacent lobe was also resected; death occurred in eight cases (60 per cent). Even with the high mortality following lobectomy, it is at present the only operation to which one can resort with reasonable hope.

Dr. Baumgartner of Paris is an advocate of bronchoscopic aspirations, both as a preparation for operation on the suppurative focus and to improve the general conditions of inoperable bronchiectatic patients. The only reliable treatment is that by which the focus is drained and the pathologic tissues are resected. In order to cause the complete disappearance of the focus the speaker advised "progressive pneumectomy," performing the fragmentary excision of pathologic lung tissues in several operations. Typical lobectomy should be reserved for bronchiectasis complicated with suppuration of the lung and also for either suppurative or nonsuppurative bronchiectasis when located in a lobe. The speaker described the technic of pneumectomy. In the first operation, by which he establishes the route of parietal approach to the pathologic area of the lung, he places around the pleura a small bundle of metallic threads which are going to serve as points of reference, to indicate in the following days, by means of the roentgen examination, whether or not the operative opening corresponds to the nearer point to the focus. These threads, after the operation, are held in place by the packing.

Dr. Ascoli of Rome stated that the older the chronic abscesses of the lung are, the more dangerous to operate. The mortality rate is 19 per cent among patients operated on before the sixth month of the evolution of the abscess, while it is 75 per cent among patients who have had the abscess for a long time. In unilobular and in multilobular abscesses, pneumotomy followed by drainage is indicated. In cases of chronic complicated suppurative conditions of the lung, only resection of the lung may be followed by recovery. Typical lobectomy is difficult and has so high a mortality rate that it should be done only in exceptional cases.

Dr. Coquelet of Brussels, in his paper, said that one should not intervene in suppuration of the lung before the fourth or sixth week of its evolution. The second month is the best time to operate. Pneumotomy is advisable when the suppurative focus is superficially located. Resection of the lung should be resorted to in diffused suppurations. The speaker advised the use of the so-called progressive fragmental pneumectomy.

Dr. M. Lagos of Barcelona advised bronchoscopic aspiration followed by intrapulmonary medication by means of intratracheal injections of liquid medicaments through a catheter placed in the main bronchus, according to García Vicente's method; also the extrapleural use of paraffin, which by promoting pleural adhesions makes more accessible the suppurative focus. In bronchiectasis without cavitation, collapse therapy gives good results; when cavitation is already present, one should resort to pneumectomy. One should resort to lobectomy only when dealing with patients in good general health and whose bronchiectatic lesions are restricted to one lobe.

Dr. Sauerbruch of Berlin said that his statistics show that of late operations on abscesses of the lung and on bronchiectasis have shown better results than those performed formerly. The better results are due to the preparation for the operation. He favors the formation of pleural adhesions in cases in which they are not already formed by means of the filling with paraffin. The operation should be performed not later than the fifth week. The speaker obtained recovery after thoracotomy in twelve patients with large central abscesses of the lung, and also in six patients with gangrene of the lung. The author stated that bronchiectasis is congenital in 80 per cent of the cases. His statistics include 623 cases of abscesses of the lung and 300 cases of bronchiectasis.

### New Surgical Society

The Sociedad Española de Cirugía has recently been organized, thanks to the activities of Dr. Goyanes, former director of the Instituto del Cancer. The membership fees are rather high, the money going to publish a journal, the organ of the society. Members must have certain qualifications and attend a minimum number of meetings. This regulation aims to prevent the lack of attendance which has been observed in several medical societies of Madrid, whose members attend the meetings only when they are on the program. Even the presidents of medical societies rarely attend the meetings, thus making it necessary to name a substitute.

### The Blind in Madrid

The civic authorities of Madrid recently gave to blind persons in Madrid 200 white canes, all alike, by means of which blind persons may be distinguished from normal pedestrians and walk with more safety in the streets.

Mr. I. Prieto, the minister of the treasury, obtained the passage of a bill by which blind employees of the treasury, when retiring, are to be pensioned with their entire salary instead of half of it, which is allowed others when retiring from duty.

### Change of Physicians at Public Health Resorts

For more than a century, there has been a body of physicians nominated by the government to supervise the sanitation of the health resorts in the provinces of Spain. Every health resort has had a physician director in charge of the sanitation and of the patients. Those physicians charged a small amount to every patient besides the salary paid to them by the government. Many of the patients who go to the health resorts have not had confidence in the physicians in charge. Perhaps that is one reason why the balnearies have not been attended by the public in the last few years. The minister of the interior has changed these physicians. The physicians in the locality to which the balneary belongs are going to take charge of the patients and of the sanitary problems of the health resorts.

# Deaths

**William Williams Keen** ⊕ President of the American Medical Association, 1900-1901, died, June 7, at his home in Philadelphia at the age of 95. He was the dean of American surgery and his repute was world-wide. Dr. Keen was born in Philadelphia, Jan. 19, 1837. He was graduated by Brown University in 1859 and received his M.D. degree from Jefferson Medical College, Philadelphia, in 1862. Honorary degrees were conferred on him by his Alma Mater, by Northwestern University, University of Toronto, Edinburgh University, Yale, St. Andrews, University of Pennsylvania, Upsala, Harvard and the University of Paris.

Dr. Keen was distinguished as a medical officer, a physician, a citizen and a socially minded man. He served his country in three wars, acting as assistant surgeon of the Fifth Massachusetts Regiment in 1861 and assistant surgeon in the United States Army from 1862 to 1864. In the Spanish-American War he was enrolled as a lieutenant in the medical corps. In the World War he was created major on April 16, 1917, and served until March 18, 1918. He was also during the World War a member of the National Research Council.

William Williams Keen, M.D., 1837-1932

After his service during the Civil War, he took up practice in Philadelphia, conducting the Philadelphia School of Anatomy from 1875 to 1876, at the same time acting as lecturer of pathologic anatomy at Jefferson Medical College. From 1876 to 1889 he was professor of artistic anatomy in the Pennsylvania Academy of Fine Arts, and from 1884 to 1889 professor of surgery in the Women's Medical College. Then he became professor of surgery in Jefferson Medical College, maintaining this position until 1907, when he became professor emeritus.

Dr. Keen was honored by numerous organizations in his specialty throughout the world. He was president of the American Surgical Association in 1899, Vice President of the American Medical Association in the same year, and the next year President. He presided at the International Congress of Surgery in Paris in 1920 and at the Congress of American Physicians and Surgeons in 1903. He had been elected a corresponding member of the Surgical Societies of France, Belgium and Italy, and he was an honorary fellow of the Royal College of Surgeons of England, Edinburgh and Ireland. His contributions to scientific research had gained for him numerous medals and awards, including the Bigelow medal of the Boston Surgical Society, the Colver-Rosenberger medal from Brown University, and the gold medal of the Pennsylvania Society of New York. Moreover, he had been awarded the Order of the Crown of Belgium in 1920 and of the Legion of Honor of France in 1923. From 1873 to the time of his death he was a fellow and trustee of Brown University.

Dr. Keen was a great surgeon and an exceptional surgical teacher. His contributions to the surgery of the brain, the spine and the nerves were recognized as of especial merit. As a surgeon he was physiologically minded. His earliest book was a work on "Reflex Paralysis and Gun-Shot Wounds" by himself and Dr. Morehouse, published in 1864. His other published works follow rapidly, including his "Clinical Charts," published in 1870; "A History of the Philadelphia School of Anatomy," in 1874; "A History of Practical Anatomy," in 1870; "A History of the First Baptist Church of Philadelphia," in 1898; "Surgical Complications and Sequels of Typhoid Fever," in 1898; a collection of "Addresses and Other Papers," in 1905; then came the publication of Keen's "System of Surgery" in eight volumes, which was repeatedly revised and which is still an established reference work i this field.

At this time Dr. Keen became especially interested in the necessity of combating the vicious attacks made by the antivivisectionists on scientific animal experimentation. He waged the battle of scientific medicine in this field almost to the hour of his death. His first series of papers on animal experimentation and medical progress was published in 1914. The Colver lectures at Brown University on human welfare were published in 1917 and his collected papers and addresses in 1922. In the meantime he continued his historical researches, printing a book on Brown University in 1914; "Selected Papers and Addresses," in 1916; "The Surgical Operations on President Cleveland," in 1917, and the book on the "Treatment War Wounds," in 1917. Among his other accomplishmen was the editing of Gray's "Anatomy" in 1887 and of t "American Text-Book of Surgery" in 1892 and 1903.

Dr. Keen was animated always by the highest ideals; h was a man of deep religious feeling. His two contributions to this field were a small book entitled "I Believe in God and Evolution," in 1922, and another entitled "Everlasting Life," published in 1924.

This brief record of the accomplishments of this extraordinary man is but an indication of the breadth of his interests and activities. Although fragile in frame and almost diminutive in stature, his intellect coupled with an extraordinary capacity for hard work brought him well merited leadership. He retired from active practice at the age of 70, saying "No man over 70 has the right to hold human lives in his hands." His gif for epigram and a simple spiritual philosophy of life gave rise to numerous statements, which were quoted both in medical and in lay literature throughout the world. His ambition to reach 100 years of age was thwarted by a failing heart, which incapacitated him and made him practically an invalid during the last three years of his life. Nevertheless he bore his retirement with fortitude and maintained practically to the moment of his death the dryly humorous attitude that made him thousands of friends during his many years. Many a man who achieves fame and who retires from active life the age of 70 is forgotten unt the time when obituaries ar transcribed. Invalid that h was, the world continued to talk of Dr. Keen until the moment of his death, and his contributions to science and to life are likely to maintain his memory for many years to come.

**Gordon Fay Willey** ⊕ Captain, U. S. Army, retired, Bedford Hills, N. Y.; University of Michigan Medical School, Ann Arbor, 1911; member of the Medical Society of the State of Pennsylvania and the American Psychiatric Association; served during the World War; entered the medical corps of the U. S. Army as a first lieutenant in 1917 and was retired for disability in line of duty in 1922; superintendent of the Bedford State Reformatory for Women; formerly superintendent of the Institution for Mentally Defective Women, Albion; aged 47; died, May 23, of self-inflicted gunshot wounds.

**Arthur Hutchins Cilley** ⊕ New York; College of Physicians and Surgeons in the City of New York, 1896; assistant professor of clinical surgery, department of orthopedic surgery, and chief of clinic, Cornell University Medical College; member of the New Hampshire Medical Society and the American Orthopedic Society; fellow of the American College of Surgeons; consulting orthopedic surgeon to the Riverside and Reconstruction hospitals, New York, and the Nassau Hospital, Mineola, N. Y.; aged 61; died, May 31, in the New York Hospital, of pneumonia.

**Charles Albert Fairbanks**, Dover, N. H.; Harvard University Medical School, Boston, 1877; member of the New Hampshire Medical Society; past president and secretary of the Strafford County Medical Society; formerly member and chairman of the school committee; formerly mayor of Dover and member of the state legislature; aged 83; died, April 30, in the Wentworth Hospital.

**George Raymond Narrley**, Keokuk, Iowa; St. Louis College of Physicians and Surgeons, 1909; member of the Iowa State Medical Society and the Associated Anesthetists of the United States and Canada; served during the World War; formerly on the staff of St. Joseph's Hospital; aged 53; died, May 8, at Rochester, Minn.

**Sidney Storrs Hall**, Minneapolis; Harvard University Medical School, Boston, 1867; an affiliate fellow of the American Medical Association; member and for many years treasurer of the State Medical Society of Wisconsin; aged 88; died, May 7, in the Eitel Hospital, of coronary arteriosclerosis and cholecystitis.

**Anthony Huffaker** ⊕ Carson City, Nev.; Cooper Medical College, San Francisco, 1890; past president of the Nevada State Medical Society; for many years on the staff of the Stanford University Hospital, San Francisco; aged 68; died, May 15, of heart disease.

**Edgar A. P. Briney**, Bloomfield, Mo.; Louisville (Ky.) Medical College, 1890; Kentucky School of Medicine, Louisville, 1890; Bellevue Hospital Medical College, New York, 1897; deputy state health commissioner; aged 71; died, April 27, of cerebral hemorrhage.

### NEW LIFE CORPORATION FRAUD

### T. J. Collier of Hot Springs, Ark., Debarred from the Mails

The New Life Corporation of Hot Springs, Ark., sometimes called New Life, Inc., sold an alleged sexual rejuvenating nostrum known as "New Life Gland Capsules." After investigation by the postal authorities, the business was declared fraudulent and denied the use of the mails.

According to a memorandum submitted to the Postmaster General by the Hon. Horace J. Donnelly, Solicitor for the Post Office Department, the New Life Corporation had for its president one Thomas J. Collier, for its vice-president Thomas J. Collier, Jr., and for its secretary and treasurer Mrs. Gossett Greer, the latter two persons being the son and daughter, respectively, of Thomas J. Collier. All of the stock was owned by Collier, Sr., except two shares held by his son and daughter.

The business consisted in the sale through the mails of New Life Gland Capsules, which were advertised under representations that, when used as directed and regardless of the age of the user or the cause of his condition, would quickly and permanently cure impotency and waning sexual power. It was also represented as being absolutely harmless and especially beneficial to sufferers from prostate gland trouble.

New Life Corporation
Hot Springs National Park, Ark.

The advertising originally was done in newspapers, but later newspaper advertising was abandoned and circulars were substituted.

When the postal inspectors investigated the case, Collier is alleged to have advised them that his capsules contained orchitic, pituitary, thyroid and suprarenal substance. When the capsules were analyzed by the federal chemists, they were found to contain, in addition to the glandular matter, extract of nux vomica and probably powdered cantharides!

In April, 1932, the New Life Corporation and Collier were called on to show cause on May 5 why a fraud order should not be issued against them. Neither Collier nor any representatives of his appeared at the time set for the hearing, but a written answer to the charges was submitted by a firm of attorneys at Pine Bluff, Ark. Judge Donnelly, in his memorandum to the Postmaster General, reported that medical expert testimony showed that the preparation would not restore lost or waning sexual power to persons taking it and it was pointed out that impotency may be due to a variety of causes and obviously no one treatment could be successful. It was also brought out that the preparation would be of no value in prostate trouble, while there was possibility of harm in the drugs and glandular substances included in the capsules: Strychnine might tend to increase nervous irritability; thyroid substance is capable of doing considerable damage; and cantharides is a violent irritant.

The memorandum also brought out the fact that Collier is not a physician, chemist or pharmacist and employed no one having such qualifications. Collier informed the Post Office Inspector that he had a colored man whom he employed to take a preparation that was secured by him from the Home Products Company of Denver—another swindle against which a fraud order was issued in August, 1931. The Negro, according to Collier, was apparently benefited by the treatment, and Collier then went to St. Louis, where he procured some capsules and administered them to some of his colored employees. He then started to sell the preparation.

Judge Donnelly reported in his memorandum that the evidence showed the scheme to be one for obtaining money through the mails by false and fraudulent pretenses, representations and promises, and he recommended that a fraud order be issued against the New Life Corporation, New Life, Inc., and T. J. Collier. Such an order was issued on May 10, 1932.

### VITAMIN CONTENT OF PINEAPPLE JUICE—SUPPLY OF VITAMIN C

*To the Editor:*—What is the vitamin content of fresh and canned pineapple juice? Please suggest means of providing vitamin C, in sufficient quantities, for artificially fed infants who show an inability to take orange juice, grapefruit juice and tomato juice.

Archibald W. Warnock, M.D., San Pedro, Calif.

Answer.—The vitamin content of canned pineapple juice is only slightly less than that of fresh pineapple juice. Pineapple juice is a fair to good source of vitamin A and compares favorably with orange juice in this vitamin. The B content also compares favorably with that of citrus fruits. Pineapple is ranked as a good source of vitamin B. Pineapple juice is less potent than orange juice in vitamin C; 1.5 cc. is the protective dose for citrus fruits in vitamin C for guinea-pigs; 2.5 cc. is the protective dose for pineapple juice; 2.5 cc. of pineapple juice represents 9 Gm. of the whole fruit. The vitamin C content of canned pineapple juice is about five-sevenths that of fresh fruit.

Strawberries and tomatoes are about equally potent in vitamin C. This vitamin C content suffers no appreciable loss through canning by usual commercial methods. Raspberries, red and white currants and gooseberries are reported to contain vitamin C and retain their antiscorbutic qualities when canned. Ripe bananas are frequently used in infant feeding and are a good source of vitamin C. Raw bananas probably contain about one third as much vitamin C as oranges. The juice of the Swedish turnip rutabaga, obtained by filtering expressed juice of freshly grated pulp through a muslin bag, is rich in antiscorbutic content. This raw rutabaga juice is advocated by the English as an inexpensive source of vitamin C for infant feeding. Potatoes contain vitamin C, although in much less concentration than do oranges and tomatoes. Cabbage is an excellent source of vitamin C and compares favorably with citrus fruit juices; 1 cc. of freshly expressed cabbage juice is protective for guinea-pigs, whereas 1.5 cc. of orange juice is the protective dose. The vitamin C content of cabbage juice is readily destroyed by heating; of rutabaga juice less so, whereas the vitamin C content of orange juice is not readily destroyed by heat.

Certain of the canned comminuted vegetables which have been accepted by the Committee on Foods are guaranteed to contain vitamin C in slightly less potency than the raw vegetables.

### POLLENS OF PENNSYLVANIA

*To the Editor:*—A man, aged 47, has attacks of asthma from May till the first frost. He lives here on the Allegheny plateau in Somerset County about 2,000 feet above sea level. He is a soft coal miner and lives in a mining town. He has no attacks in Harrisburg or in Brooklyn. The attacks are more severe at night when the dew is on the ground and the air is damp. The attacks are worse when it rains and worst immediately after rains. What are the possible causes? What pollens are found in this section of Pennsylvania? What pollens are found here and not around Harrisburg or Brooklyn? Please omit name and address.

M.D., Pennsylvania.

Answer.—With the meager details given, only the most general suggestions can be offered. Of the four diagnostic points, the geographic clue seems the least reliable as it involves so many considerations not subject to adequate control. The seasonal occurrence of symptoms points strongly to pollen, but it must be remembered that atmospheric concentration of pollen is low at night, and during and after it rains the air is almost or entirely pollen free. Also there is no single kind of pollen in Pennsylvania that could account for symptoms continuing from May until frost. Nevertheless, pollen should be given first consideration and careful skin tests should be made with all possible pollen offenders, including the late-blooming trees, the common grasses and all summer and fall hay fever weeds.

Other seasonal possibilities are seasonal foods, seasonal clothing, insects, insecticides and other contacts incidental to seasonal recreation and occupations. These would include animal emanations, pyrethrum, garden vegetables and fruits.

Walzer, in "Hay Fever and Asthma" (Springfield, Charles C. Thomas, 1931), says: "The etiology of purely seasonal attacks is not always obvious. A baffling type of case is that known as summer asthma, which, although constantly seasonal, seems to bear no relation to any known atopen or physical agent in the patient's environment."

No local field or atmospheric studies of hay fever pollen have been made in Somerset County. Both field studies and atmospheric pollen counts have been made at Pittsburgh, Philadelphia and New York. Only field observations have been made at Harrisburg.

There is little difference in the variety of hay fever plants found in these localities. Tree pollen is, of course, more common in Somerset County than in Brooklyn. Symptoms in the patient under consideration do not begin during the season of pollination of the earlier trees. The oaks, walnut and hickory are the principal trees pollinating in May. Hay fever grasses are much the same throughout Pennsylvania. Bluegrass is probably the most common offender in Somerset County. Its period of pollination is late May and June. Other grasses continue to furnish pollen until about the middle of July. During the latter half of July and the first week of August there is little pollen of any kind in the air. Toxic concentrations of ragweed pollen begin to appear on pollen slides in Pittsburgh, Philadelphia and New York soon after the 10th of August. The apex is reached about the first of September, and the season is practically over by the last week of September. During this time at least 95 per cent of the pollens found on the slides is from the common ragweeds. In a mining community it is not likely that there are large areas of cultivated ground, and it is quite possible that the ragweed pollen concentration is comparable to that encountered in the cities. There could be local intimate contacts with the pollen of other weeds than ragweed. A local study by a competent botanist would be advisable.

The potential hay fever pollens of southwestern Pennsylvania are as follows, the most important ones being marked with an asterisk:

| Common Name | Botanic Name | Time of Pollination |
|---|---|---|
| Trees: | | |
| Maple | Acer spp. | March–April |
| Alder | Alnus spp. | March–April |
| Hazelnut | Corylus americana | March |
| *Elm | Ulmus spp. | March |
| Hornbeam | Carpinus caroliniana | April |
| Ironwood | Ostrya virginiana | April |
| Birch | Betula spp. | April |
| Ash | Fraxinus spp. | May |
| *Oak | Quercus spp. | May |
| Walnut | Juglans nigra | May |
| Hickory | Hicoria spp. | May |
| Grasses: | | |
| *Bluegrass (June grass) | Poa pratensis | May–June |
| Orchard grass | Dactylis glomerata | June |
| *Timothy | Phelum pratense | June–July |
| Redtop | Agrostis palustris | June–July |
| Corn | Zea mays | July–August |
| Weeds: | | |
| Red sorrell | Rumex acetosella | May–June |
| English plantain | Plantago lanceolata | July–September |
| Pigweed | Amaranthus retroflexus | June–September |
| *Short ragweed | Ambrosia elatior | August–September |
| *Giant ragweed | Ambrosia trifida | August–September |
| Cocklebur | Xanthium commune | August–September |

## CIRCULATORY DISTURBANCES OF THE EXTREMITIES

*To the Editor:*—A man, aged 35, has had good health except for mitral regurgitation; his compensation is good. Whenever he walks to any extent, he complains of aching and cramping in the muscles of his legs. When this takes place, the legs often contract and he has acute pain. After the patient has rested for one or two hours, the condition disappears. Please advise what your diagnosis may be and whether myalgia could be a factor in the case. Please omit name.

M.D., Oklahoma.

ANSWER.—This description suggests intermittent claudication, which, however, must be considered as a symptom and not a disease. There is undoubtedly a neurocirculatory element underlying the condition, possibly located in the sympathetic nerve.

The aching and cramping should be considered danger signals that there is a disturbance of the neurocirculatory apparatus of the extremity. One would suggest that roentgenograms be made of the limbs in an attempt to demonstrate arteriosclerosis. The myalgia is undoubtedly secondary. The muscle hypertonicity and the neurocirculatory disturbance create a vicious circle.

In addition to roentgenograms of the legs, the patient should have a careful examination for mechanical defects of the feet, such as flatfoot and short achilles tendon.

The physician would do well to consult Buerger's book on Circulatory Disturbances of the Extremities (W. B. Saunders Company).

## STROPHANTHUS AND DIGITALIS

*To the Editor:*—What is the relative danger of using strophanthus and digitalis? Is it as dangerous as textbooks would lead one to think? Most textbooks say it should not be repeated more than once in twenty-four hours and should be used with extreme caution if digitalis has been recently given. Solis-Cohen's Pharmacology recommends that, when digitalis is used for an extended period, it be tapered off and on with strophanthus. If a patient was seen with an acute heart failure and strophanthus was given once and still more medication should be needed, can you give me some idea as to the amount of digitalis that might be used with safety, provided, for example, it would take 20 cc. of digitalis to digitalize the patient? Kindly cite any literature.

DAVID MITCHELL BLUM, M.D., Des Moines, Iowa.

ANSWER.—Strophanthus, as such, has no legitimate place in the therapeutics of heart disease, because it is absorbed poorly and irregularly, and all its effects are produced more certainly and more safely by digitalis. There is no basis in fact for the statement in the textbook that it is necessary to alternate between digitalis and strophanthus when the former is used for an extended period of time, because the two drugs have the same kind of action on the heart. The content of some of the questions suggests that the inquiry refers to strophanthin or ouabain rather than to the crude drug strophanthus. Ouabain (crystalline strophanthin) has a limited field of usefulness, and this only in occasional cases of acute heart failure. In such cases, in which the patient is moribund, the total intravenous dose of ouabain may be regarded as 1 mg., provided the patient has not had digitalis within ten days, that dose being about equivalent to the total oral dose of 2 Gm. of digitalis, or 20 cc. of the tincture which is required to produce full digitalization. It would be fairly safe in a case such as that cited to give 0.5 mg. of ouabain intravenously at once, followed immediately by an oral dose of 5 cc. of tincture of digitalis. A dose of 5 cc. of the tincture might then be given every six to eight hours until the full therapeutic effects or minor toxic symptoms have been obtained. This technic is used for very rapid digitalization, and there are dangers involved in such doses; but, on the other hand, unless the patient is at the point of death there is rarely any justification for the intravenous use of strophanthin.

A study of the intravenous injection of ouabain in man is reported in a paper by Wyckoff and Goldring (*Arch. Int. Med.* **39**:448 [April] 1927). They give references to the literature.

## SUBACUTE BACTERIAL ENDOCARDITIS

*To the Editor:*—A woman, aged 20, who had had articular rheumatism, chronic heart disease with valvular lesions and enlargement of the myocardium, contracted influenza about two months ago. The acute conditions subsided in three weeks, followed, after a short period, by a remittent fever, from 99 to 104 F. While the patient was rapidly losing weight, her skin assumed a café au lait hue, with rare punctiform petechiae on the skin and mucous membranes. In an institution, a diagnosis was made of subacute bacteremia; three consecutive blood cultures were found positive for Streptococcus viridans. The patient has been treated with parenteral blood injections, sodium salicylate, 4 Gm., in starchy enemas, digitalis, and codeine, with slight advantage. No use has been made of transfusion, bacteriophage vaccine or streptococcus serum because they have not been deemed of advantage. Is there any other treatment which could make the prognosis less fatal in this case? Is there any percentage of recovery? Kindly omit name.

M.D., New York.

ANSWER.—From the description of the case, of a woman of 20 with a history of rheumatic heart disease with a remittent fever for a month or more, associated with pallor, petechiae, and blood cultures positive for Streptococcus viridans, it would appear extremely likely, if not certain, that the patient is suffering from a subacute bacterial endocarditis. There are a few additional points that one would look for to amplify the diagnosis, such as hematuria, other embolic phenomena, enlargement of the spleen, and Osler nodes, but even without these, the diagnosis seems definitely established. Assuming that this is so this disease is well nigh uniformly fatal in spite of any and all treatment, although countless procedures have been recommended and tried. There have been a few cases observed by competent trained clinicians in which recovery has occurred, or at least remissions for a considerable period, going into years, but even in such instances these remissions or recovery are usually spontaneous in character and not, so far as current knowledge goes, due to any specific type of treatment.

A baffling type of case is that known as summer asthma, which, although constantly seasonal, seems to bear no relation to any known atopen or physical agent in the patient's environment."

No local field or atmospheric studies of hay fever pollen have been made in Somerset County. Both field studies and atmospheric pollen counts have been made at Pittsburgh, Philadelphia and New York. Only field observations have been made at Harrisburg.

There is little difference in the variety of hay fever plants found in these localities. Tree pollen is, of course, more common in Somerset County than in Brooklyn. Symptoms in the patient under consideration do not begin during the season of pollination of the earlier trees. The oaks, walnut and hickory are the principal trees pollinating in May. Hay fever grasses are much the same throughout Pennsylvania. Bluegrass is probably the most common offender in Somerset County. Its period of pollination is late May and June. Other grasses continue to furnish pollen until about the middle of July. During the latter half of July and the first week of August there is little pollen of any kind in the air. Toxic concentrations of ragweed pollen begin to appear on pollen slides in Pittsburgh, Philadelphia and New York soon after the 10th of August. The apex is reached about the first of September, and the season is practically over by the last week of September. During this time at least 95 per cent of the pollens found on the slides is from the common ragweeds. In a mining community it is not likely that there are large areas of cultivated ground, and it is quite possible that the ragweed pollen concentration is comparable to that encountered in the cities. There could be local intimate contacts with the pollen of other weeds than ragweed. A local study by a competent botanist would be advisable.

The potential hay fever pollens of southwestern Pennsylvania are as follows, the most important ones being marked with an asterisk:

| Common Name | Botanic Name | Time of Pollination |
|---|---|---|
| Trees: | | |
| Maple | Acer spp. | March–April |
| Alder | Alnus spp. | March–April |
| Hazelnut | Corylus americana | March |
| *Elm | Ulmus spp. | March |
| Hornbeam | Carpinus caroliniana | April |
| Ironwood | Ostrya virginiana | April |
| Birch | Betula spp. | April |
| Ash | Fraxinus spp. | May |
| *Oak | Quercus spp. | May |
| Walnut | Juglans nigra | May |
| Hickory | Hicoria spp. | May |
| Grasses: | | |
| *Bluegrass (June grass) | Poa pratensis | May–June |
| Orchard grass | Dactylis glomerata | June |
| *Timothy | Phelum pratense | June–July |
| Redtop | Agrostis palustris | June–July |
| Corn | Zea mays | July–August |
| Weeds: | | |
| Red sorrell | Rumex acetosella | May–June |
| English plantain | Plantago lanceolata | July–September |
| Pigweed | Amaranthus retroflexus | June–September |
| *Short ragweed | Ambrosia elatior | August–September |
| *Giant ragweed | Ambrosia trifida | August–September |
| Cocklebur | Xanthium commune | August–September |

## CIRCULATORY DISTURBANCES OF THE EXTREMITIES

*To the Editor:*—A man, aged 35, has had good health except for mitral regurgitation; his compensation is good. Whenever he walks to any extent, he complains of aching and cramping in the muscles of his legs. When this takes place, the legs often contract and he has acute pain. After the patient has rested for one or two hours, the condition disappears. Please advise what your diagnosis may be and whether myalgia could be a factor in the case. Please omit name.

M.D., Oklahoma.

ANSWER.—This description suggests intermittent claudication, which, however, must be considered as a symptom and not a disease. There is undoubtedly a neurocirculatory element underlying the condition, possibly located in the sympathetic nerve.

The aching and cramping should be considered danger signals that there is a disturbance of the neurocirculatory apparatus of the extremity. One would suggest that roentgenograms be made of the limbs in an attempt to demonstrate arteriosclerosis. The myalgia is undoubtedly secondary. The muscle hypertonicity and the neurocirculatory disturbance create a vicious circle.

In addition to roentgenograms of the legs, the patient should have a careful examination for mechanical defects of the feet, such as flatfoot and short achilles tendon.

The physician would do well to consult Buerger's book on Circulatory Disturbances of the Extremities (W. B. Saunders Company).

## STROPHANTHUS AND DIGITALIS

*To the Editor:*—What is the relative danger of using strophanthus and digitalis? Is it as dangerous as textbooks would lead one to think? Most textbooks say it should not be repeated more than once in twenty-four hours and should be used with extreme caution if digitalis has been recently given. Solis-Cohen's Pharmacology recommends that, when digitalis is used for an extended period, it be tapered off and on with strophanthus. If a patient was seen with an acute heart failure and strophanthus was given once and still more medication should be needed, can you give me some idea as to the amount of digitalis that might be used with safety, provided, for example, it would take 20 cc. of digitalis to digitalize the patient? Kindly cite any literature.

DAVID MITCHELL BLUM, M.D., Des Moines, Iowa.

ANSWER.—Strophanthus, as such, has no legitimate place in the therapeutics of heart disease, because it is absorbed poorly and irregularly, and all its effects are produced more certainly and more safely by digitalis. There is no basis in fact for the statement in the textbook that it is necessary to alternate between digitalis and strophanthus when the former is used for an extended period of time, because the two drugs have the same kind of action on the heart. The content of some of the questions suggests that the inquiry refers to strophanthin or ouabain rather than to the crude drug strophanthus. Ouabain (crystalline strophanthin) has a limited field of usefulness, and this only in occasional cases of acute heart failure. In such cases, in which the patient is moribund, the total intravenous dose of ouabain may be regarded as 1 mg., provided the patient has not had digitalis within ten days, that dose being about equivalent to the total oral dose of 2 Gm. of digitalis, or 20 cc. of the tincture which is required to produce full digitalization. It would be fairly safe in a case such as that cited to give 0.5 mg. of ouabain intravenously at once, followed immediately by an oral dose of 5 cc. of tincture of digitalis. A dose of 5 cc. of the tincture might then be given every six to eight hours until the full therapeutic effects or minor toxic symptoms have been obtained. This technic is used for very rapid digitalization, and there are dangers involved in such doses; but, on the other hand, unless the patient is at the point of death there is rarely any justification for the intravenous use of strophanthin.

A study of the intravenous injection of ouabain in man is reported in a paper by Wyckoff and Goldring (*Arch. Int. Med.* **39:**448 [April] 1927). They give references to the literature.

## SUBACUTE BACTERIAL ENDOCARDITIS

*To the Editor:*—A woman, aged 20, who had had articular rheumatism, chronic heart disease with valvular lesions and enlargement of the myocardium, contracted influenza about two months ago. The acute conditions subsided in three weeks, followed, after a short period, by a remittent fever, from 99 to 104 F. While the patient was rapidly losing weight, her skin assumed a café au lait hue, with rare punctiform petechiae on the skin and mucous membranes. In an institution, a diagnosis was made of subacute bacteremia; three consecutive blood cultures were found positive for Streptococcus viridans. The patient has been treated with parenteral blood injections, sodium salicylate, 4 Gm., in starchy enemas, digitalis, and codeine, with slight advantage. No use has been made of transfusion, bacteriophage vaccine or streptococcus serum because they have not been deemed of advantage. Is there any other treatment which could make the prognosis less fatal in this case? Is there any percentage of recovery? Kindly omit name.

M.D., New York.

ANSWER.—From the description of the case, of a woman of 20 with a history of rheumatic heart disease with a remittent fever for a month or more, associated with pallor, petechiae, and blood cultures positive for Streptococcus viridans, it would appear extremely likely, if not certain, that the patient is suffering from a subacute bacterial endocarditis. There are a few additional points that one would look for to amplify the diagnosis, such as hematuria, other embolic phenomena, enlargement of the spleen, and Osler nodes, but even without these, the diagnosis seems definitely established. Assuming that this is so this disease is well nigh uniformly fatal in spite of any and all treatment, although countless procedures have been recommended and tried. There have been a few cases observed by competent trained clinicians in which recovery has occurred, or at least remissions for a considerable period, going into years, but even in such instances these remissions or recovery are usually spontaneous in character and not, so far as current knowledge goes, due to any specific type of treatment.

## PERSISTENT SINUS FOLLOWING DRAINAGE OF EMPYEMA

*To the Editor:*—One year ago I did first a closed and then later an open operation for empyema, which was caused, our hospital pathologist said, from gangrene of the lung. He based his diagnosis on the character of the aspirated fluid. The patient had a stormy convalescence but finally made a good recovery and has taken on considerable weight. He still has a sinus in the left posterior axillary region extending upward from about the tenth rib for 5 inches. Repeated roentgen examinations have failed to disclose any bronchial fistula, and injection of the sinus with iodized oil before roentgenography does not reveal any communicating sinuses, and there is no infection of the ends of the excised rib. This sinus is about the size of a number 22 French catheter and has so far resisted all efforts looking toward its closure. Lately it has been dressed every four days and each time a clean drainage tube about 3½ inches long inserted. It has been irrigated with iodine solution, permanganate solution, saline solution and surgical solution of chlorinated soda, and lately following the irrigation I have been injecting the sinus through the drainage tube with bismuth paste. I have also used at different times 1 per cent and stronger silver nitrate solution. The man is now in excellent health and for the past six months has been doing his full quota of work in an admistrative position. What have you to suggest looking toward the closure of this sinus other than the radical operation? Please omit name.

M.D., Wisconsin.

Answer.—The common causes of a persistent sinus following drainage in empyema are bronchial fistula, osteomyelitis of resected rib stumps, and a foreign body, such as a sequestrum from a rib stump. The failure to demonstrate a fistula by the roentgenogram following injection of contrast mediums does not exclude the possibility of a small sinus capable of keeping up enough infection to prevent healing. The history of a severe pulmonary infection at the onset of the illness is consistent with the development of a bronchial fistula.

Since the fistula has failed to heal following the use of conservative measures, a radical operation involving the unroofing of the sinus from its source to the outlet is indicated.

## TOXIC EFFECTS OF ARSPHENAMINES

*To the Editor:*—I have read with the greatest interest an excellent paper on the toxic effects of the arsphenamines and wish to congratulate the author on the efficient manner in which he has dealt with this difficult problem. I would like to ask, however, whether any of the six deaths of hemorrhagic encephalitis recorded among 78,350 injections have occurred immediately after or not later than half an hour after the injection. A case, which I have heard about recently, occurred one and one-half hours later, but no autopsy could be performed by the physician. It would be rather difficult to explain it by a nitritoid crisis and vascular shock. As far as I know, no pathologic changes had been found before the injection (urine, temperature) and the dose of 0.3 Gm. had been well tolerated before.

C. M. Hasselmann, M.D., Manila, P. I.

Answer.—It is difficult to answer this question, because of insufficient data concerning the stage of the disease, the type of syphilitic involvement, and the number of doses of arsenicals already given. The history of a sudden death sounds rather suggestive of a hemorrhagic encephalitis, however. Ordinarily these cases come early in the course of the treatment of syphilis. The usual picture is that of a fresh syphilis in which the patient has been given two or three or more injections of the arsenicals. Following the last dose, within a period of twenty-four to thirty-six hours, the patient is taken with symptoms of headache, dizziness and vomiting. The picture quickly goes on to that of unconsciousness, stiffness of the neck, and even opisthotonos. If a lumbar puncture is done, the fluid is found to be under high pressure and there may be an increased cell count. As a rule, death ensues within forty-eight to seventy-two hours.

## PHOSPHATURIA IN DIABETIC PATIENT

*To the Editor:*—1. Is "phosphatic diabetes" generally admitted to be a type of diabetes? If so, what treatment is recommended for the phosphaturia? 2. In arranging a diet for a diabetic patient is there a decided advantage in distributing the carbohydrate allowance beyond three or four meals daily?

H. S. Smythe, M.D., Bristol, Tenn.

Answer.—1. Phosphaturia is a common enough condition and is usually of no particular significance. It is thought that there is a relation between phosphaturia and the activity of the nervous system. The term "phosphatic diabetes" is used for a comparatively rare illness the symptoms of which are polyuria, thirst, emaciation, and a great increase in the excretion of phosphates, which rise to as much as from 7 to 9 Gm. a day. Not much is known about the latter condition. The treatment for phosphaturia is a combination of measures directed toward stabilization of the nervous system and correction of dietary errors. A plentiful supply of water should be used.

2. In arranging a diet for a diabetic patient the distribution of the carbohydrate allowance is best determined by a fractional analysis of the urine. It is well known that diabetic patients do not all behave in the same manner regarding the sugar output. In one patient the main excretion of sugar will be early in the morning and in another patient it will be late in the day. Activity and exercise apparently help some diabetic patients to utilize sugar. On the other hand, rest has the same effect on others. It is obvious that the distribution of the carbohydrate is a matter for individual determination.

## HIGH DIASTOLIC-LOW PULSE PRESSURE

*To the Editor:*—Will you kindly give me the latest information on treatment and the interpretation of a high diastolic and a low pulse pressure. I am greatly concerned over my own pressure, which registers constantly systolic from 135 to 150 and diastolic from 110 to 122. The pulse pressure ranges from 25 to 28 and the pulse rate from 80 to 95. Please omit name.

M.D., Texas.

Answer.—The interpretation of the high diastolic-low puls pressure requires further study. More data are needed, particularly along the lines of kidney function, age of patient and habits. A persistent diastolic pressure between 110 and 122 is likely to indicate some disturbance of renal function. Usually this disturbance indicates a disease of the renal-vascular system. Information on treatment is not advisable until the additional data are determined.

## ORTHODONTIA

*To the Editor:*—I have under my observation a girl, now 14 years of age, who has worn orthodontia appliances for a period of two years under the rigid supervision of an expert in that field, and the result obtained, so far as the alinement of the teeth is concerned, is excellent and all that one might expect. Is it possible for this treatment to cause an arrested growth of the mandible, causing the facial appearance of a retreating chin? This condition is now present; it was not in earlier life, nor is it a family characteristic. Kindly omit name.

M.D., Utah.

Answer.—In the development of malocclusions it often pens that between the ages of 8 and 14 the mandible fails develop in proportion to the maxilla, probably because improper function and improper distribution of mechani forces through occlusion. In many of these cases the alinem of the teeth in the separate arches is quite perfect. The co ditions described are not uncommon in the development of t malocclusion, but probably they could not be produced as t result of treatment. If the treatment is related to the condi tion, it is because the developing malocclusion has not bee corrected. In general, orthodontic treatment stimulates growth and in most orthodontic cases the condition to be overcome is one of underdevelopment. It sometimes happens that overdevelopment of the maxilla as a result of treatment gives the appearance of underdevelopment to a normal mandible. The first important consideration to be noted in such a case is the occlusal relation of the teeth, including the relation of their long axes.

## IMMUNIZATION TO DIPHTHERIA

*To the Editor:*—A graduate nurse, aged 22, had one course of toxin-antitoxin in 1922, a second course in 1930, and one course (four doses of toxoid) in 1931-1932 (completed, Jan. 6, 1932). Schick tests after each of these courses were markedly positive. The last Schick test was made, April 1, 1932. Can you suggest any method of immunization in this case?

H. O. Pope, M.D., Latham, Ill.

Answer.—If a retest remains positive, further immunizat with diphtheria toxoid should be carried out, beginning w 0.1 cc. of toxoid and increasing the doses at weekly interv as follows: second dose, 0.25 cc.; third dose, 0.5 cc.; four dose, 1 cc.; fifth dose, 1.5 cc. The retest might then be ma two weeks after the fifth dose.

## CHONDRODYSTROPHIA FETALIS, OR ACHONDROPLASIA

*To the Editor:*—For the satisfaction of a mother who is heart broken over a child of which I delivered her with the condition known as chondrodystrophy or achondroplasia, I should like you to let me know whether or not any means of therapy has been successful.

M.D., Toronto.

Answer.—There is a definite glandular type of chondrodystrophy or achondroplasia, but no one has proved whether the relationship is one of cause and effect or coincidence. There is no harm in well regulated glandular therapy in this condition. The subject is fully discussed in an article by Philip Lewin and Edward L. Jenkinson in the *American Journal of Roentgenology and Radium Therapy* **11**:155 (Feb.) 1924. That article also provides a bibliography.

### RAYNAUD'S DISEASE

*To the Editor:*—On exposure to cold the fingers of a woman, aged 23, single, and otherwise in good physical condition, become white and numb; the area of discoloration involves the two distal phalanges of the fingers of each hand. This trouble began about two years ago in the right hand but now has involved both hands, and of late posture, that is, holding the hand aloft, as when reading a paper, produces the same phenomena. Blood examination, the Kahn test and urinalyses are all negative. The blood pressure is 100 systolic and 60 diastolic; the pulse is 70; the basal metabolic rate is 0 per cent. Chemical examination of the blood revealed creatinine, 1.8 mg.; urea nitrogen, 15.4 mg.; urea, 32.7 mg. A roentgenogram of the chest did not reveal any pathologic changes. I would appreciate any suggestions that you might have for the treatment or advice in regard to further investigation as to the diagnosis. I have thought of a possibility of an early stage of Raynaud's disease.

Richard K. Collins, M.D., Aurora, Ill.

Answer.—The clinical picture in this case is that of early Raynaud's disease. There is no satisfactory medical treatment although many patients are benefited by a change of climate especially if they can be transferred from a section of the country in which the weather is cold and damp to a section where the air is warm and dry. The more advanced cases of Raynaud's disease are being successfully treated by the surgical removal of sympathetic ganglions. In the early cases in which there is a great deal of discomfort and partial disability the operation should be considered.

### EXCESSIVE DRYNESS OF SKIN

*To the Editor:*—A white man, aged 29, a decided blond, weighing 165 pounds (75 Kg.) and 5 feet 11½ inches (180 cm.) in height, apparently in good health, complains of excessive dryness of the skin. He states that this condition has existed for several years. Once or twice during a year the outer layers of the skin of the hands and feet "peel off" in small areas. His hair is exceedingly dry. During the summer months he has profuse perspiration of the feet, hands and face and practically no perspiration of the rest of his body. Physical examination reveals no abnormalities other than confirmation of the symptoms described. A high fat content diet apparently has no beneficial effects. I would appreciate any information as to etiology and treatment. Please omit name.

M.D., Kentucky.

Answer.—Excessive dryness of the skin may be hereditary or acquired. If hereditary, it may represent a first degree ichthyosis or xeroderma. Treatment for this condition is purely palliative. Inunctions with oil of theobroma (cacao butter) or any bland fat may be prescribed. An acquired dryness of the skin and hair may be of hypothyroid origin. A basal metabolism test would give valuable information on this point. If the reading is low, small doses of thyroid would be indicated.

### OPTIC ATROPHY AFTER TRYPARSAMIDE

*To the Editor:*—A man, aged 54, who has had syphilis since he was 17 years old, came to me complaining about total blindness. Six months previously he had a siege of severe shooting pains in his legs; a local physician administered tryparsamide intravenously, 2 Gm. once a week for six weeks. The patient complained after the second injection that his eyes grew dim. He claimed that his vision was good with the use of glasses. After the sixth injection he discovered that he could not see with his right eye, so he discontinued the treatment. The pain gradually disappeared, and at the same time the left eye became dimmer and dimmer, until he became totally blind. There has been no history of pain in the eyes. Ophthalmoscopic examination shows pallor of the disk, with an apparently normal fundus in the left eye. The right eye shows a moderate degree of atrophy of the optic nerve, with a normal fundus. The left eye is able to recognize light. Is there any antidote for tryparsamide? Any treatment you can recommend for this patient will be gratefully received. Please omit name.

M.D., California.

Answer.—Unfortunately, there is nothing known to ophthalmologic science that can restore vision in optic atrophy. The destructive effects of the tryparsamide persist long after the drug has been completely eliminated from the body, and consequently eliminative treatment would be useless.

### BRUSHLESS SHAVING CREAMS

*To the Editor:*—Please advise through The Journal as to the safety of the brushless shaving creams now on the market. I refer particularly to Barbasol, Barmami and similar types of soaps. Will the continuous use of these have any serious effect on the nervous system or skin? Please omit name.

M.D., Utah.

Answer.—Brushless shaving creams as a type are essentially mixtures of potassium stearate soap, unsaponified stearic acid, glycerin and water. From 25 to 50 per cent of the stearic acid is saponified, the other 75 to 50 per cent being free. In the formation of the soap there is a certain amount of glycerin liberated. The stearic acid is slightly irritating and occasionally it is found that these soaps irritate the skin, but as a rule they do no harm.

# Council on Medical Education and Hospitals

## COMING EXAMINATIONS

Alabama: Montgomery, July 11. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Montreal, Sept. 17. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

Arizona: Phoenix, July 5-6. Sec., Dr. B. M. Berger, 12 North Central Ave., Phoenix.

California: San Francisco, July 11-14. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Colorado: Denver, July 5. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Connecticut: *Regular.* Hartford, July 12-13. *Endorsement.* July 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic.* New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

District of Columbia: *Basic Science.* Washington, June 29-30. *Regular.* Washington, July 11-12. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

Hawaii: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Room 48 Young Bldg., Honolulu.

Illinois: Chicago, June 28-July 1. Supt., Mr. Paul B. Johnson, Springfield.

Maine: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr., 192 State St., Portland.

Massachusetts: Boston, July 12-14. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

Mississippi: Jackson, June 28-29. Asst. Sec., Dr. R. N. Whitfield, Jackson.

National Board of Medical Examiners: Examinations in Parts I and II will be held at all centers where there are five or more candidates, but not at Durham, Minneapolis, nor New Haven, June 27-29. Ex. Sec., Mr. Everett S. Elwood, 225 South 15th St., Philadelphia.

New York: Albany, Buffalo, New York, Syracuse, June 27-30. Chief, Professional Examinations Bureau, Mr. Herbert J. Hamilton, Room 315 State Education Bldg., Albany.

North Dakota: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, Grand Forks.

Oregon: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5-9. Sec., Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

Rhode Island: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

South Carolina: Columbia, June 28. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

South Dakota: Waubay, July 19. Dir., Dr. H. R. Kenaston, Bonesteel.

Utah: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

Washington: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

West Virginia: Harpers Ferry, July 12. Sec., Dr. W. T. Henshaw, State Health Dept., Charleston.

Wisconsin: Milwaukee, June 28-30. Sec., Dr. Robert E. Flynn, 315 State Bank Bldg., LaCrosse.

## Arizona April Report

Dr. B. M. Berger, secretary, Arizona Board of Medical Examiners, reports the written examination held at Phoenix, April 5-6, 1932. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Six candidates were examined, all of whom passed. Five physicians were licensed by reciprocity with other states. The following colleges were represented:

| College | PASSED | Year Grad. | Per Cent |
|---|---|---|---|
| University of Arkansas School of Medicine | | (1928) | 83.1 |
| Rush Medical College | | (1931)* | 82.6 |
| University of Louisville School of Medicine | | (1928) | 81.4 |
| Tulane University of Louisiana School of Medicine | | (1928) | 91.7 |
| Osteopaths | | | 75, 79.5 |

| College | LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|---|
| [illegible] | | (1898) | Arkansas |
| [illegible] | | (1907) | Ohio |
| hiladelphia | | (1908) | Utah |
| ool of Medicine | | (1920) | Penna. |
| Department | | (1905) | Tennessee |

* This applicant has completed his medical course and will receive his M.D. degree and license on completion of an internship.

## New Mexico April Report

Dr. P. G. Cornish, Jr., secretary, New Mexico Board of Medical Examiners, reports the written examination held at Santa Fe, April 11-12, 1932. The examination covered 12 subjects and included 100 questions. An average of 75 per cent was required to pass. Three candidates were examined, all of to be capable of satisfactorily replacing the galenic preparation of ergot for clinical use, because with them the range between effective and harmful doses is too small. On the other hand, ergotamine promises to be clinically useful as a depressant of the sympathetic nervous system, in conditions such as hyperthyroidism. The book closes with a chapter on the galenic preparations of ergot, with their preservation, pharmaceutic assaying and forensic detection, and a bibliography of forty-three pages.

**Le soufre en biologie et en thérapeutique.** Par M. Loeper, professeur à la Faculté de médecine de Paris, et L. Bory. Paper. Price, 65 francs. Pp. 341, with 41 illustrations. Paris: G. Doin & Cie, 1932.

This is an admirable presentation of the rôle of sulphur in medicine, including veterinary practice and homeopathy. The subject matter is divided into four parts, with an appendix on technic. The first part, on the biology of sulphur, is subdivided into chapters on the elementary physicochemistry, the metabolism of sulphur, its rôle in the composition of the lipoids, albumins and pigments, and the excretion of sulphur through the biliary, urinary, pulmonary and other channels. Following these is an interesting chapter on the assimilation of the element, with especial reference to the principal organs acting as depots. The final chapter in the biologic section gives a short but clear outline of the rôle of sulphur in disease, discussing pneumonia, typhoid, tuberculosis, cancer and diabetes. The second part is concerned with therapy. Under various subdivisions, the forms of the drug, its toxicity, the pharmacology, both organic and inorganic, modes of application, methods of preparation, and diseases amenable to sulphur therapy are discussed in a conservative and practical way. A special section is devoted to the location of the most famous sulphur springs and the methods used at each of them. The importance of sulphur in vegetable biology, its occurrence in soil and water and its uses in fertilizing mixtures are also given consideration. The closing sections on therapy present the indications for the use of sulphur. Its application in articular and respiratory disease, dermatology and syphilis, general infections, nutritional disturbances, gynecology, urology, and homeopathic and veterinary medicine, are discussed in turn. The formulary includes most of the best known combinations, with specific directions for compounding. Under technic, the most recent and practical methods for the demonstration of sulphur in the urine and blood are described. The book presents a thorough and yet conservative evaluation of the place of sulphur in modern therapy. It may be recommended to the general practitioner, the research worker and particularly the dermatologist.

**A Diabetic's Own Cook Book.** By Stella H. Lyons. With a foreword by Logan Clendening. Cloth. Price, $2. Pp. 94. New York: Alfred A. Knopf, 1932.

As book after book is added to the already comprehensive library of literature on diabetes, the evaluation of additional volumes becomes steadily more difficult and necessitates discriminating criticism. Additional volumes should at least justify their publication either by a unique presentation of old material or by the introduction of new material of clinical or pathologic value. The author of the present volume has purposely limited her audience to fellow diabetics and has succeeded in producing a workable guide to assist them in cooking and planning balanced meals of limited carbohydrate content. She has increased the value of her cook book by the introduction of three autobiographic chapters written in semiserious, optimistic style, free from technical phrases. By this personal history she is able to warn against the inevitable consequences of "cheating" in the diet and to suggest some practical daily precautions that have benefited her. These confessions are apt to carry more weight than the warnings of physicians. The remaining chapters carry out the real mission of the book as stated by the author, "to remove that bugaboo, scales, for the layman who has not the time to study and transcribe measurements" and "to give a few rules and recipes," which are the product of years of experimentation in her own kitchen. Some of the most useful features of the book include directions for home canning of fruits and vegetables, transcription of gram and ounce measurements into the more familiar but equally accurate teaspoons, tablespoons and cups, and of course many appetizing recipes with food values computed. The general format of the book is inviting and avoids all semblance to a medical textbook. This volume will prove helpful to diabetic patients as a practical guide to daily dietary planning and as a supplement to any of the standard manuals of diabetes.

**L'ostéose parathyroïdienne et les ostéopathies chroniques.** Par J.-A. Lièvre, médecin assistant à l'Hôpital Trousseau. Paper. Price, 60 francs. Pp. 389, with 30 illustrations. Paris: Masson & Cie, 1932.

Lièvre summarize eighteen reported cases of parathyroid adenomectomy. Two of these were personal observations; in addition, a necropsy of one of his cases in which operation was refused is described in detail. These cases are used to describe definitively the syndrome due to parathyroid adenomas or overactivity. Necropsies of various bone diseases are reviewed with respect especially to the bones and parathyroids. From this critical review he brings out clearly what is the rôle of the parathyroid in bone diseases and what bone disorders are probably not related to parathyroid disease. Details of the pathologic anatomy and roentgenologic pictures of the bones are given. The chemical make-up of the blood is discussed as well as the balance studies on calcium metabolism. A valuable bibliography is appended. The book will prove especially useful to those interested in bone diseases, parathyroid diseases or disturbances in calcium metabolism.

**Research Work on the Pneumococci and Their Enzymes and Its Significance in Lobar Pneumonia.** By A. Cowan Guthrie, M.B. Cloth. Price, 7/6. Pp. 60, with 13 illustrations. London: Baillière, Tindall & Cox, 1932.

A careful reading of this volume indicates that it is hardly worthy of extended consideration in a scientific publication.

## Pedicle of Ovarian Tumor Twisted by Accident

*(Winthrop v. State Industrial Commission (Calif.), 2 P. (2d) 142)*

The claimant, an employee in a shoe store, stood on a stool to reach merchandise on a shelf. The stool tipped and she fell backward to the floor. The date of the accident she fixed as Jan. 13 or 14, 1930, although she was not certain. The date apparently made no clear impression on her mind because she did not at first attribute her disability to the accident and made no immediate demand on her employer for compensation or for medical treatment. Her employer claimed that the accident occurred between January 2 and 5, but the employee was certain that it could not have occurred as early as January 2. At the time of her fall she was dazed, but she continued to work until January 18. Then she had to stop. It was not until January 25, however, that she summoned her personal physician. On January 27 she was taken to a hospital, suffering from intense abdominal pain, fever and delirium. On January 31 she was operated on, and a large ovarian tumor and her left ovary were removed. The tumor was attached by a pedicle, which had become twisted in two places, cutting off the blood supply to the tumor and causing a gangrenous condition. The employee later claimed compensation under the workmen's compensation act, which the industrial accident commission refused to grant. The claimant thereupon took the case by certiorari to the Supreme Court of California.

The uncontradicted evidence, said the Supreme Court, shows that symptoms of which the claimant was free at the time of her accident began to develop almost immediately thereafter and became increasingly acute until an operation was performed. Those experts who observed the claimant's symptoms within a short time after the fall were of the opinion that the fall caused them. The experts who held to a contrary view did not see her until after the operation and they based their opinions largely on the premise that the preoperative symptoms did not appear sufficiently soon after the accident to indicate that they had any connection with it. The medical experts all recognized, expressly or impliedly, that a fall may cause the twisting of the pedicle of a tumor. While neither the cause of the twisting of the pedicle nor the time when it occurred was susceptible of exact demonstration, the physicians who attended the claimant and personally observed the position and condition of the tumor and contiguous organs and tissues were in a better position to judge the length of time the condition had been in developing than were those whose calculations were based only on related facts. The claimant's failure to attribute her severe pain to the accident does not prevent her recovering compensation, if the accident was the origin or the accelerating cause of her disability. She had suffered previous attacks of abdominal pain, but she was unaware that she had a tumor. A recurrence of her abdominal pain may have indicated to her a return of her previous complaint rather than a changed pathologic condition resulting from her accident. An employee is not to be deprived of compensation because she fails to make a correct medical diagnosis.

The order of the industrial accident commission denying compensation to the claimant was reversed, four of the justices concurring. The chief justice and two associate justices dissented, holding that under the circumstances of the case the finding of the industrial accident commission was a finding of fact, supported by adequate evidence, which could not properly be disturbed by the court.

### Liability for Not Completing Operation

*(Britton v. Hartshorn (Conn.), 156 Atl. 48)*

The plaintiff, on advice of her physician, entered a hospital at Derby, to be operated on by the defendant, for the removal of a uterine tumor. The tumor filled the entire abdomen. The preoperative examination indicated that it was probably cystic or fibrocystic. The defendant, according to his evidence in the suit that followed, told the plaintiff that if he found the growth too involved to permit its removal without danger to life, no extensive operation would be performed, to which the plaintiff assented. On making the preliminary incision, the defendant found an entirely fibrous tumor, fed by numerous large blood vessels, firmly adherent to various organs and to the body wall, and securely lodged in the pelvis. After conferring with his associates who were assisting him, he concluded that to undertake to remove the tumor with the resources then at hand would endanger the plaintiff's life; that it was better that it should be removed later at the New Haven General Hospital, where he usually operated, where he had trained assistants who were accustomed to his technic, where donors were immediately available if transfusion of blood became necessary, and where numerous surgeons were available as assistants in the operating room in case of an emergency. He therefore closed the incision, and the plaintiff, according to the evidence of the defendant, made a rapid and uneventful recovery. When she had recovered from the anesthetic she was advised by the defendant to enter the New Haven Hospital to have the operation performed. This, however, she did not do, but after eighteen months' medical treatment by other physicians she was successfully operated on elsewhere, by another physician.

The plaintiff was dissatisfied because of the failure of the defendant to remove the tumor at the operation in the hospital at Derby. She alleged that because of that operation she had suffered from phlebitis and shock and had incurred expense in obtaining a cure. She contended that at no time was anything said to her about the operation being an exploratory operation for the purpose of ascertaining the kind of tumor or its size or extent, or about any operation other than an operation to remove it, and that it was to an operation for the removal of the tumor that she consented. She therefore sued to recover damages. The case was tried by a jury. The defendant offered expert opinion evidence that he had used due care and skill in his operation and in his treatment and care of the plaintiff and had used excellent judgment in refusing to continue the operation under the circumstances under which it was being performed. Verdict and judgment were given for the defendant. The plaintiff thereupon appealed to the Supreme Court of Errors of Connecticut.

The trial court instructed the jury that:

> Negligence and unskilfulness are not presumed; they must be proved. In the absence of evidence to the contrary, the law will presume from the physician's right to exercise his profession that he has not violated his duty to exercise it with the requisite care and skill.

The court had previously told the jury that the plaintiff had to prove the essential controverted facts alleged in her complaint and later it charged the jury that she had to prove by the preponderance of evidence the occurrence of the acts or omissions necessary to show that ordinary skill had not in fact been exercised. To the instruction quoted, the plaintiff took exception. In an action by a physician for compensation for his service, said the Supreme Court, the burden of proof so far as relates to his carefulness and skilfulness is satisfied by the theory of law, which from evidence of the right of a physician to practice his profession presumes that he has not violated his duty to practice it with the requisite care and skill, and a defendant in such a case, who contends that his physician did not exercise such care and skill, must prove by a preponderance of evidence the acts or omissions constituting the alleged violation of the physician's duty. The same principle, in essence, is applicable in a malpractice case and requires the plaintiff to introduce evidence to support his allegations of want of care or skill, before the defendant is called on to produce evidence on that issue. The burden is on the plaintiff ultimately to establish want of care or skill, by a preponderance of evidence. The instruction given by the trial court could not well have been understood otherwise than as stating the rule, supported by overwhelming authority, that if the plaintiff introduces no evidence of lack of proper care and skill, the defendant is entitled to prevail on that issue without producing evidence to support it, because of the implications that arise from his right to practice his profession.

It was proper, said the Supreme Court, for the trial court to instruct the jury that the fact that the result of an operation was not as favorable as hoped for by the patient or by the physician raises no presumption of want of proper care and skill. Likewise was proper the supplementary comment by the court that medical and surgical science has not been so perfected "that a complete cure can be assured."

In undertaking to clarify to the jury the terms of the contract between the plaintiff and the defendant, the trial court stated what the defendant claimed: "that the contract was to treat the plaintiff's ailment with proper care and skill, and in no event would he endanger her life, and that when, during the course of the operation, it became apparent to him that to complete it under the then existing circumstances might endanger her life, he complied with his agreement by taking no further steps to remove the tumor." And the trial court then charged the jury:

> If you find this to have been the agreement of the parties, and that the defendant did not remove the tumor for the reason that to have done so would have endangered the plaintiff's life, and that his conduct was in accord with the standard of due care and skill previously given you, then the contract would not have been breached.

The plaintiff, however, took exception to this instruction, apparently because it did not take into account her claim that with proper care and skill the defendant could have determined before commencing the operation whether the tumor could safely be removed at that time and place, and her claim that, having undertaken the operation, it was his duty to proceed with it to completion, by removing the tumor. Here, said the Supreme Court, the trial court was considering the defendant's claim as to the terms of his agreement with the plaintiff. The plaintiff's claims as to those terms were adequately covered in other parts of the court's charge.

To a hypothetical question propounded to an expert witness, to obtain his opinion as to whether there was lack of skill or care on the part of the defendant, the plaintiff objected that the hypothetical question related to the ultimate issue of negligence or unskilfulness, which was a matter to be determined by the jury. This objection, however, said the Supreme Court, was invalid as applied to a case of this kind. In such a case, opinion evidence on the main issue of professional care and skill, "being a topic requiring special experience of an expert," is not only permitted, but required, to be produced by the plaintiff. To controvert such opinion evidence, the defendant may introduce similar evidence. It remains the province of the jury to consider and weigh conflicting opinions and to determine from them whether proper professional skill and care were exercised.

The Supreme Court of Errors found no error in the case and the verdict and judgment in favor of the defendant therefore stood.

## COMING MEETINGS

American Ophthalmological Society, New London, Conn., June 27-29. Dr. Emory Hill, 501 East Franklin Street, Richmond, Va., Secretary.
Medical Library Association, San Francisco, June 20-22. Miss Marjorie J. Darrach, 645 Mullett Street, Detroit, Secretary.
Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.
Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.
South Dakota State Medical Association, Watertown, June 20-22. Dr. John F. D. Cook, Langford, Secretary.
Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.
West Virginia State Medical Association, Parkersburg, June 21-23. Mr. J. W. Savage, Professional Building, Charleston, Executive Secretary.
Wyoming State Medical Society, Rock Springs, July 18-19. Dr. Earl Whedon, 50 N. Main Street, Sheridan, Secretary.

## MEDICAL ASSOCIATION OF GEORGIA

*Eighty-Third Annual Session, held at Savannah, Ga., May 17-20, 1932*

The President, Dr. Arthur G. Fort, Atlanta, Ga., in the Chair

### Tuberculosis of the Kidney

Dr. Wallace L. Bazemore, Macon, Ga.: Eleven urologists in Georgia report to me that they have made a definite diagnosis in sixty-eight cases of renal tuberculosis in the past five to ten years. The diagnosis of urinary tuberculosis depends on finding the organism in the urine. When better laboratory facilities become available, more cases will be diagnosed. With the continued efforts of the profession to eradicate pulmonary tuberculosis, fewer and fewer renal infections will be seen. The removal of a tuberculous kidney or a tuberculous epididymis, with neglect of a distant focus, only invites further urinary involvement.

### Biopsy

Dr. Everett L. Bishop, Atlanta, Ga.: No hard and fast rule can be made to apply to biopsy in general, for in certain cases it does no apparent harm, and frequently it is necessary for diagnosis. It must be admitted that in some cases the procedure is fraught with considerable danger to the patient and in these cases other means at hand will give almost or just as much information as will the microscopic examination of an extremely small piece of tissue. There are a few general rules that should be considered when performing biopsy for diagnosis. In certain conditions it is always advisable to remove the entire tumor rather than to excise only a small piece. The removal of the entire tumor is more desirable in tumors of the skin if they are small, or single lymph nodes or indefinite tumors of the breast. No encapsulated tumor should be incised; rather, the entire tumor should be removed intact. It should always be remembered that the biopsy gives a picture of one portion of the tumor only, which may be entirely misleading and for this reason it is an extremely dangerous method of diagnosis in bone tumors. In tumors of bone so situated that amputation cannot be done or in multiple tumors of bone, it is doubtful whether biopsy is ever justified. Biopsy is of great value in establishing a diagnosis in suspected tumors of the larynx, when early diagnosis is essential for any hope of cure. Suggestive lesions of the lip are probably best treated with radiation without biopsy on account of the liability of early metastases. Rectal tumors usually are so situated that biopsy can be easily done, but one should be careful to obtain a piece of the tumor and not simple hyperplastic mucosa. Methods of biopsy are varied. The cautery coagulates the tissue and, unless a relatively large piece is removed by this method, the entire specimen will be coagulated and useless for diagnostic examination. Biopsy by needle puncture, with an 18 gage needle and ordinary syringe, has lately been employed, its advantage being that there is almost no appreciable trauma and it can be used for deep tumors when one would hesitate to cut down on them. Recently I have used the Hoffman punch, a trocar instrument with a larger bore than the ordinary needle used in the foregoing method. With this instrument it is frequently possible to remove a fragment of the tumor large enough for embedding and sectioning. In using this instrument, it is necessary to incise the skin under procaine before introduction. The advantage of this instrument lies in the fact that a small but frequently diagnostic biopsy can be done on deep seated tumors with little trauma and little discomfort to the patient.

### Cosmetic Dermatology

Drs. Jack W. Jones and Herbert S. Alden, Atlanta, Ga.: Deviations from the normal skin which do not seriously injure the health of the individual but are disagreeable to the patient may be spoken of as "cosmetic skin complaints." Such skin lesions as benign nevi (moles and angiomas), superfluous hair, pigmentations, scars, freckles, tattoo marks, acne, warts, leukoderma and telangiectases all come under this heading. More and more people are seeking relief of their real or supposed cosmetic defects, and the medical profession should lead in the dissemination of correct knowledge and application of the valuable aids at hand for the removal of these defects. Let us have a more careful consideration of the patient seeking cosmetic advice. Many of these individuals may cause themselves much damage by turning to the unintelligent beauty operator for advice.

### Treatment of Sinusitis

Dr. Calhoun McDougall, Atlanta, Ga.: The wave of radicalism in sinus surgery is on the wane. It is being realized that more conservative treatment, such as immunization with vaccines or nonspecific therapy, climate and diet, are more efficacious than surgery in many cases. Conservative surgical procedures in sinus disease, in cooperation with natural defense and healing processes, frequently prove of tremendous value. In critical conditions they may turn the tide, averting a fatal outcome, by timely drainage of pus. The objectives are to establish aeration and drainage.

### Vitamin Therapy

Dr. D. H. Garrison, Tate, Ga.: Study of vitamins from a physiologic and therapeutic standpoint has led to the conclusion that the human system cannot survive without the proper intake of vitamins and that it is as important to have a balanced intake of vitamins as it is to have a balanced intake of food supply. No one vitamin, prescribed alone, can give the proper results, but vitamins must be prescribed in a group, or at least the mater vitamin A should be prescribed with any other vitamin in order to obtain the proper results.

### Observations of Some Common Breast Lesions

Dr. William Perrin Nicolson, Jr., Atlanta, Ga.: Let me urge a careful examination and consideration for every patient with a breast lesion. One should determine first of all whether it is inflammatory or a new growth and, if the latter, whether benign or malignant and, if malignant, the degree of malignancy. Such conditions as benign hypertrophy should be recognized early when the breast can be saved, and Brodie's disease when an apparently hopeless condition can be cured with simple amputation. Irradiation with x-rays or radium or both should be given in hopeless cases, and in suitable cases a palliative operation performed. Lastly, the doctrine of periodic health examinations should be spread, and one should remember that every solitary lump in a breast should be removed and examined by a competent pathologist. If a pathologist is not available it is safer to remove the breast instead of the lump, and then a delay of a week or ten days before the radical operation can be performed is not so hazardous.

### The Relation of Diseases of the Nasal Accessory Sinuses to Systemic Derangements

Dr. William Mithoefer, Cincinnati: The nasal accessory sinuses play an important rôle in the causation of systemic derangements. The infection in the nasal sinuses is often of a latent type, with frequent acute exacerbations, and consequently is often overlooked by the practitioner who does not use the instruments of precision necessary for the detection of disease within the cavities. It is a sad commentary to see patients who have had a bronchitis treated for several months without consideration of the nasal accessory sinuses as a cause of the infection of the lower respiratory tract. It is a great sin of omission on the part of the rhinologist to look on disease of the nose and its ramifying cavities as a local disturbance only, and to ignore entirely the fact that many times there is present a constitutional derangement. They term us specialists of the ear, nose and throat; it would be more to the point if we were just plain doctors who are making a special study of the ear, nose and throat.

### Effect of Previous Ligation of the Common Duct on Restoration of the Liver Following Partial Hepatectomy

Dr. J. Gaston Gay, Atlanta, Ga.: Experiments were performed on dogs to determine whether the liver would be restored after partial removal, if jaundice was produced by previous obstruction to the outflow of bile. The routine procedures were as follows: The common bile duct was ligated and the gallbladder removed. At various intervals after the production of biliary obstruction, two or more lobes of the liver were removed. It was found that partial removal of the liver was not followed by the remarkable restoration that occurs in the normal liver.

### Origin and Development of the Psychoneuroses

Dr. Lewis M. Gaines, Atlanta, Ga.: The psychoneuroses for their development require a favorable soil. This is furnished in a large percentage of cases by unfavorable heredity; in a smaller percentage, by various types of physiologic deficiencies, such as dietary or endocrine, or by preexisting disease, infectious or noninfectious. Reynolds found impairment of normal physiologic function of the body an etiologic factor in 42.5 per cent of 200 cases. Physical injuries leading to traumatic neuroses should be considered in this category and are of particular interest to railroad and industrial surgeons. In individuals thus conditioned, emotion, particularly fear, in some guise, or interference with the fundamental instincts of self-preservation and sex life, are the important effective causes. These causes extend back almost invariably to an early period of life—to infancy or early childhood. Symptoms develop gradually, reaching their zenith as a rule during puberty or early maturity. A case of pure psychoneuroses appearing for the first time after the age of 25 is rare and suggestive of other disease. The feeling of inferiority as described by Adler in response to unfavorable environment is doubtless responsible for the development of many cases. The mechanism so elaborately worked out by Freud may be operative in a certain number but certainly not in the majority. Because of the frequency of psychoneuroses, the degree of misery they bring and the all too common mistakes in diagnosis, it is of the greatest importance for all physicians to obtain as clear an insight as possible into the mechanisms responsible.

### Gastro-Intestinal Manifestations of the Psychoneurotic State

Dr. Russell H. Oppenheimer, Atlanta, Ga.: As practitioners of medicine grow away from the type of the old time family doctor, they lose their position as confidant and counselor. This changed position tends to make them unaware of the experiences and thoughts of the patient. They know little of his joys and sorrows, his apprehensions and fears, his anxieties. Lacking this information and the inclination or time to acquire it, they have but one course left: to ascribe the patient's complaint to some organic (structural) disturbance, which they treat sometimes symptomatically, sometimes specifically (they think) and sometimes surgically. Often the benefit, if any, derived under these circumstances is due largely to chance or to the hopes of the patient and is generally but transient in character. The interrelation of the autonomic and the central nervous system permits psychic influences to alter the functional activity of the gastro-intestinal tract. Because of the wide variation of demands made on it, the gastro-intestinal tract is especially suscepticle to such psychic influences. The functional difficulties thereby established give rise to symptoms similar to the symptoms induced by organic diseases, as these symptoms also arise largely from functional disturbance. The symptoms of this psychic alteration of gastro-intestinal function are the gastro-intestinal manifestations of the psychoneurotic state.

### Cardiac Manifestations of the Psychoneurotic State

Dr. Ernest F. Wahl, Thomasville, Ga.: Functional disorders of the heart may result from a number of direct causes. A casual remark by an insurance examiner that a murmur is present, that the heart skips a beat, or advice given by the family physician that the heart should be watched may initiate a life of chronic invalidism. On the other hand, the patient may assume the presence of a serious lesion because he is examined by more than one physician. A thorough diagnostic study, including all indicated laboratory procedures, must be made before treatment is to be considered. Special attention should be given to the patient's environment as possible causes of psychic stimuli. Drugs should play an insignificant rôle in the treatment of functional disorders of the heart. Cardiac stimulants should be avoided. Some simple sedative is sometimes necessary at the beginning but should be discontinued as soon as possible. A few cases of premature contraction will respond only to quinidine.

### The Treatment of the Psychoneurotic State

Dr. W. R. Houston, Augusta, Ga.: My advice to those undertaking psychotherapeutic treatment for the cure of functional disorders is not to be diverted into the bypaths of surgery or pharmacology. The solution will ultimately be found by one who is determined to do so. One should go at the problem, not bound by any system or by any set of rules; but all the skill, all the knowledge of man that one has been able to accumulate will be called into play.

### Effects of Injections of Ovarian Follicular and Anterior Pituitary Hormones on Conception and Pregnancy in Laboratory Animals

Dr. G. Lombard Kelly, Augusta, Ga.: Small doses of female sex hormone (as low as 10 rat units), given in broken doses, will prevent conception in the guinea-pig. When the dosage is increased to 75 units and more, abortions and miscarriages result, though in the later stages of pregnancy the young perish in utero and the mothers often die also. Injections of freshly expressed juice of anterior pituitary or of the extract of pituitary-like hormone from the urine of pregnant women into sexually mature female guinea-pigs just after copulation does not prevent conception. Injections of the same two products into pregnant animals almost invariably cause abortion or miscarriage. Whether the results obtained in this investigation are due to the hormones or to other substances contained in the injected material remains to be determined.

### A Method of Traction for Fractures of the Femur

Dr. Charles H. Watt, Thomasville, Ga.: In the method herein described, counteraction is obtained by the use of a "running trunk" plaster-of-paris spica cast fastened to the head of the bed by means of ropes attached to metal strips incorporated in the cast. During the past six months I have used this procedure in ten cases. One of the patients suffered fractures of both femurs, making a total of eleven fractures. The youngest patient was a boy of 14, and the oldest was a man aged 72. Eight were males and two females. The longest stay in the hospital was fourteen days and the shortest five days, with an average of nine and one-half days. The feeling is that better anatomic and functional results are being obtained than formerly.

### The Physician's Part in the Public Health Program

Dr. J. A. Redfearn, Albany, Ga.: It is the duty of physicians to urge employment of county or district health officers and to support the several departments of public health. Private practitioners are backward in developing preventive medicine. Correcting physical defects that one may find or have pointed out by health officers is not enough. Mental hygiene should be stressed by physicians. Public health will be greatly benefited through advice by physicians on dietetics. Physicians are prone to fail to explain the importance of a balanced diet. Mothers will permit their children to eat unbalanced diets in the midst of plenty until malnutrition, pellagra, tuberculosis or rickets develops, while physicians retain unspoken messages, fearful that motives might be misconstrued.

### How Much Curative Medicine Should a Health Department Do?

Dr. C. L. Ridley, Macon, Ga.: Had the medical profession done the things advocated by health departments and accepted by the profession as worthy and worth-while measures in the prevention of disease there could never have been any excuse for the existence of health departments as now operated. When the medical profession assumes its place in preventive medicine with every man, everywhere, doing the things he should to prevent avoidable disease and premature death, the activities of health departments can be restricted to a more limited field. It is imperative at present that health departments go into the field of preventive medicine absolutely unhampered and with the hearty support of the medical profession till such a time as the medical profession is ready to assume the responsibility of disease prevention as well as the care of those who are ill.

### Rickets

Dr. Mercer Blanchard, Columbus, Ga.: Rickets often begins to develop in the first few weeks of life; treatment must be begun early. Three important agents are available: cod liver oil, viosterol (irradiated ergosterol) and sunlight (natural or artificial). It is my custom to start cod liver oil at about a week or 10 days of age in a dosage of 15 minims (1 cc.). In about ten days, this is given twice a day. The dosage is gradually increased until three teaspoonfuls a day is given at 3 months of age. I frequently add a drop or two of viosterol to each dose of cod liver oil. When the weather permits, sun baths are started, beginning with a few minutes a day and gradually increasing to half an hour. There is so much opposition on the part of the mothers to undressing the babies in cool weather, for fear of cold, that I begin just exposing the legs and face to the sun rays. I have about twenty babies that were handled along this line, this winter and spring, at the same time getting cod liver oil or viosterol. The results have been fine. The curative treatment of rickets is the same as the prophylactic, only more active. Larger doses of cod liver oil or viosterol are given, and this is combined with treatment with the mercury vapor lamp. The various foods that have been activated act as adjuncts in the treatment.

### The Common Cold

Dr. A. J. Waring, Savannah, Ga.: I venture to make the following suggestions for the prevention of colds in childhood: One should see that the child's nose, throat and accessory cavities are not pathologic, diagnosing early and remedying allergic manifestations if possible. Exposure to infections of the mucous membranes should always be avoided; if exposure has occurred, silver salts should be used intranasally for three days. One should see that his food, clothing and rest are suitable, that he has abundant fresh air, that he is never anemic, and that his skin reacts quickly to heat and cold. Let him avoid marked chilling and fatigue. In other words, if he is not a normal child physically and psychically, he should be worked over sympathetically until he becomes one. It seems to me that the best a pediatrician can strive for is to see that at the age of puberty the boy or girl leaving his office for the last time leaves it with a courageous mind and a vigorous body. Toward the attainment of that object, the avoidance or the prompt cure of the common cold is a strategic move of inestimable value.

### Intracranial Birth Hemorrhages

Dr. C. M. Burpee, Augusta, Ga.: Intracranial hemorrhages are responsible for many of the deaths that occur during the first few days of life and most of the paralyses seen in childhood. They are frequently not recognized at birth. They occur most frequently in the premature infant or the infant subjected to a long, difficult labor, particularly when instrumentation, podalic version with breech extraction or solution of pituitary is used to terminate this type of labor. They are always due to intracranial trauma. The hemorrhage may occur anywhere inside the skull, but subdural hemorrhages are the most important. The symptoms depend on the size and location of the hemorrhage. The prognosis depends not only on the size and location of the hemorrhage but on the type of treatment instituted. The treatment consists in prevention as far as possible by appropriate prenatal care. All prolonged or difficult labors should be considered as potential cases of intracranial hemorrhage and treated as such. Respiration should be stimulated by a mixture of carbon dioxide and oxygen rather than by violent resuscitative measures. All infants with intracranial hemorrhage or suspected intracranial hemorrhage should be put at absolute rest and external heat applied when necessary. The increased intracranial pressure should be relieved and the respiration maintained. The body fluid should be maintained and, above all, the infant should be watched closely. *In large supratentorial hemorrhages the blood clot may be removed if adequate surgical facilities are available.*

### Carcinoma of the Colon

Dr. M. J. Egan, Savannah, Ga.: As much progress has been made in the past ten years in surgery of the carcinoma of the colon, as regards both operative mortality and end-results, as in any other field of surgery. The greatest aid to early diagnosis of growths in the colon proper is the x-rays, with which diagnosis and localization can be made with fair accuracy in more than 95 per cent of the cases. I cannot emphasize too strongly in this regard that the barium should be used as an enema after cleaning out the colon and not as a meal which completely closes a small opening through the growth, causing an acute obstruction to be superimposed on an already chronic obstruction. Carcinoma of the colon calls for surgical treatment, with resection of the growths if recognized at a favorable time before extension by metastasis and adhesion to surrounding viscera takes place; otherwise by colostomy proximal to the growth. The large majority are best treated by graded operations and only in early carcinoma of the right half of the colon is primary resection and ileocolostomy justifiable, and even then an ileostomy should be done proximal to the site of the anastomosis or the closed end of the colon brought up against the wound with long sutures, which come out through the upper end of the wound, so that if gas does accumulate and cannot be expelled this end of the colon can be opened to prevent breaking down of the suture line. When normal function of the bowel becomes established, this opening closes spontaneously. In practically all other cases a colostomy well proximal to the growth or an ileostomy, if the growth is in the cecum, should be done as a preliminary procedure, with a wait of from ten days to two weeks or longer if necessary to build up the patient's resistance and get the growth and bowel in favorable condition for resection. In carcinoma of the colon without metastasis and under local conditions in which removal is possible, the prognosis is as satisfactory as for carcinoma in other parts of the body and better than for carcinoma in any other part of the gastrointestinal tract.

### Amebiasis: Prevalence and Protean Manifestations

Drs. S. F. Rosen and David R. Thomas, Jr., Augusta, Ga.: The treatment of our patients consisted of 1 grain (0.065 Gm.) of emetine hydrochloride intravenously for ten days. Most writers recommend subcutaneous and intramuscular injection, but these are quite painful and we have never had any untoward reaction from its intravenous use. We give 1 grain diluted to 10 cc. with physiologic solution of sodium chloride. This is followed by a course of chiniofon. The usual treatment consists of 16 grains (1 Gm.) three times a day by mouth over a period of ten days and in refractory cases a 250 cc. enema of 2 per cent chiniofon, especially when the ulcers are in the lower portion of the colon, since the drug is supposed to act by direct contact with the amebas. Emetine is not without danger, but when cautiously administered is quite useful. Cases of peripheral neuritis have been reported and it too may set up a diarrhea. Emetine is a depressant to the heart, and sudden death has been reported following its use; but if one gives only 1 grain daily in well diluted solutions, gives it slowly and does not exceed 10 grains in as many days, there will be no untoward results. Treatment, however, should not be repeated within six to eight weeks because emetine is eliminated very slowly.

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to The Journal in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

### American Journal of Medical Sciences, Philadelphia

*Nature of Physical Signs of Bundle-Branch Block. J. T. King and D. McEachern, Baltimore.—p. 445.

Unusual Atropine Effect on Ventricular Tachycardia. S. M. Salley, Boston.—p. 456.

Congenital Heart Disease with Multiple Cardiac Anomalies: Report of Case Showing Aortic Atresia, Fibrous Scar in Myocardium and Embryonal Sinusoidal Remains. S. Bellet and B. A. Gouley, Philadelphia.—p. 458.

Incidence of Thrombo-Angiitis Obliterans in Brothers. S. S. Samuels, New York.—p. 465.

*Erythromelalgia and Other Disturbances of Extremities Accompanied by Vasodilatation and Burning. G. E. Brown, Rochester, Minn.—p. 468.

Blood Pressure in Arteries of Extremities in Normal Subjects and in Patients with Peripheral Vascular Disease. H. E. Pearse, Jr., and J. J. Morton, Rochester, N. Y.—p. 485.

*Coronary Disease in One Hundred Diabetics. M. H. Nathanson, Minneapolis.—p. 495.

Diabetic Gangrene: Incidence and Pathogenesis: Analysis of Fifty-Eight Cases Among One Thousand and Eight Diabetics. D. W. Kramer, Philadelphia.—p. 503.

Effect of Lugol's Solution on Chronic Lymphatic Leukemia and Its Bearing on Pathogenesis of Exophthalmic Goiter. H. B. Friedgood, Ann Arbor, Mich.—p. 515.

Food Allergy in Differential Diagnosis of Abdominal Symptoms. A. H. Rowe, Oakland, Calif.—p. 529.

Syphilitic Arthritis with Effusion. D. H. Kling, New York.—p. 538.

Aseptic Purulent Meningitis: Report of Six Benign Cases. G. A. Young and A. E. Bennett, Omaha.—p. 550.

Spasmodic Torticollis: Results of Removal of Foci of Infection and Treatment with Specific Vaccine. E. H. Rynearson and H. W. Woltman, Rochester, Minn.—p. 559.

Clinical Cycle of Goiters. J. W. Hinton, New York.—p. 563.

**Physical Signs of Bundle-Branch Block.**—In an analysis of fifty consecutive cases of bundle-branch block, King and McEachern noted the following physical signs: visible reduplication of the apex thrust in forty-two (84 per cent), palpable reduplication in forty (80 per cent), first heart sound split into two elements in twenty-eight (56 per cent), two separate systolic murmurs in six (12 per cent), and a single first sound with a separate murmur in eight (16 per cent). On the basis of these signs a correct diagnosis was made prior to knowledge of the electrocardiogram in thirty-four of forty attempts (85 per cent); the presence of bundle-branch block was suspected in two (5 per cent) but was not definitely diagnosed; the diagnosis was not made in 4 (10 per cent). There was a difference of opinion in four other cases. In the remaining six cases, the presence of bundle-branch block was recognized only by electrocardiogram. In three patients showing complete auriculoventricular block as well as intraventricular block, the diagnosis of both conditions was made in two cases from clinical signs and the signs were equally clear in the third case; signs of bundle block were found and this condition recognized clinically in five of seven patients showing both fibrillation and bundle block. The latter two groups of cases show that the auricles are not concerned with the physical signs of bundle block. Presystolic gallop bears a superficial resemblance to the signs of bundle block: however, clinical evidence and apex cardiograms show the two conditions to be different, presystolic gallop being truly presystolic, and the signs of bundle block being limited to systole and causing a division of the apex systolic plateau. Normal controls failed to show systolic reduplication. A cinematographic film of the movement of a straw attached to the cardiac apex showed a double systolic thrust in each of five consecutive cases of bundle-branch block. On the basis of their observations, the authors draw the following conclusions: 1. Intraventricular block may be recognized in a majority of cases from physical signs. 2. The most constant signs consist of visible and palpable reduplication of the apex thrust. 3. The reduplication is within systole. The auricles do not play a part in the production of the physical signs.

**Erythromelalgia and Other Disturbances of Extremities.**—Brown calls attention to the fact that the term erythromelalgia is not entirely accurate, since redness and pain in the extremities are common to several vascular diseases of diverse types. In erythromelalgia attacks of local vasodilatation with increased local heat and pain constitute the basic disturbance. Four fundamental criteria are essential to diagnosis of the disease: (1) bilateral burning pain in the extremities; (2) sharp increase of local heat in the affected parts, though redness, flushing or congestion may vary in degree; (3) production and aggravation of the distress by heat and exercise, and (4) relief by rest, cold and elevation. During the attacks the temperature of the affected parts should be found to reach or exceed 33 or 34 C. (91.4 or 93.2 F.) and pain usually becomes evident when this temperature is reached or exceeded. Augmentation in arterial pulsation and the rate of loss of heat give further evidence of the high degree of dilatation of the arteries. The author outlines certain methods of study to distinguish between the different conditions in which burning extremities occur.

**Coronary Disease in Diabetic Persons.**—Nathanson reports that an analysis of 100 necropsies on diabetic persons showed an incidence of 41 per cent of severe coronary disease. Above the age of 50 years the incidence was 52.7 per cent, as compared with 9 per cent in an even larger series of nondiabetic persons of the same age. The frequency of coronary disease is almost as high in the female as in the male. The incidence of hypertensive hypertrophy of the heart indicates that hypertension is only slightly more frequent in the diabetic than in the nondiabetic person. In diabetic persons with gangrene, the incidence of coronary disease is higher than in the uncomplicated cases. The essential cardiac lesion of diabetes is coronary sclerosis. Other types of cardiac disease are of relatively rare occurrence.

### American Journal of Tropical Medicine, Baltimore

**12:** 101-197 (March) 1932

*Quinine Analysis of Blood, with Reference to Treatment of Malaria. J. H. St. John, Washington, D. C.—p. 101.

*Studies in Blackwater Fever: Part I. Variation in Intensity of Hemoglobinuria Following Administration of Quinine by Regulation of Dosage of Quinine in Susceptible Individual. U. Brahmachari, P. Brahmachari and R. Banerjea, Calcutta, India.—p. 117.

Quinine and Plasmochin Therapy in Plasmodium Rouxi Infections, with Further Notes on Effects of These Drugs on Other Avian Malarias. R. D. Manwell, Syracuse, N. Y.—p. 123.

Effect of Four Amebicidal Drugs on Tissues of Digestive Tract Grown in Vitro. M. J. Hogue, Philadelphia.—p. 149.

Simple Method of Immobilizing Animals for Laboratory Purposes. L. H. Dunn, Panama, R. de P.—p. 173.

**Quinine Analysis of Blood.**—On the basis of analyses of quinine in the blood by the technic of Vedder and Masen, St. John draws the following conclusions: 1. The administration of a single dose of 1.95 Gm. of quinine sulphate in capsules to four individuals resulted in the development of a concentration of quinine in the blood of three to more than 6 mg. per liter. Analyses in two of the four showed that the concentration decreased after the first eight hours and in one it had decreased to less than one half of the maximum noted at the end of twenty-four hours. 2. The administration of 650 mg. o quinine sulphate in capsules every eight hours to two individuals resulted in the development in both, and maintenance in one of a concentration of quinine in the blood in excess of 6 mg. per liter. 3. The administration of 325 mg. of quinine sulphate in capsules every four hours to five individuals resulted in the development of a concentration of quinine in the blood, in three in excess of 6 mg. per liter, while the remaining two failed to develop this concentration. 4. The administration of 650 mg of quinine sulphate in capsules every four hours to ten individuals resulted in the development and maintenance of concentrations of quinine in the blood in excess of 10 mg. per liter in eight, while the remaining two failed to maintain this concentration. 5. The analyses made within two hours after the administration of quinine sulphate in capsules shows tha the time of the development of the highest concentration o quinine in the blood is variable. 6. It was shown that the height of the concentration of quinine in the blood, *following* the administration of divided doses of 1.95 Gm. of quinine sulphate, depends on the proportion of this amount of quinine received prior to the analysis. If given at one dose a high concentration results within a few hours to decline gradually, while small divided amounts result in low initial concentrations to reach a maximum only after the entire 1.95 Gm. of quinine has been given. 7. Continued administration of quinine in the same doses used during the first twenty-four hours does not necessarily result in increased concentrations of quinine in the blood over the maximum observed during the first twenty-four hours. In fact, after several days of the administration a slight decrease may occur. Apparently the cumulative action of the drug is countered by an increased rate of disposal. 8. A comparison of concentrations of quinine in the blood following the administration of quinine sulphate in capsules discloses that a few individuals do not develop and maintain blood concentrations as readily as others, while some develop and maintain concentrations in excess of the average. This fact may partially explain why in some of the standard quinine treated cases of malaria the patients have a relapse while others respond so readily and are cured.

**Studies in Blackwater Fever.**—The Brahmacharis and Banerjea describe experiments from which they conclude that the erythrocytes in cases of blackwater fever following administration of quinine are slightly more vulnerable to quinine than those of normal individuals. There is no difference in the vulnerability of erythrocytes in cases of blackwater fever to quinine: (1) before hemoglobinuria; (2) during active hemolysis after administration of quinine, and (3) after the disappearance of the hemoglobinuria. The increased vulnerability of erythrocytes in cases of blackwater fever to the action of quinine is so slight that it cannot account for blackwater fever that may follow quinine administration, and, therefore, whatever may be the mechanism of hemoglobinuria following administration of quinine, there is no evidence to show, so far as experiments in vitro are concerned, that it is due to any direct action of quinine on the erythrocytes of susceptible individuals.

## Annals of Internal Medicine, Ann Arbor, Mich.

5: 1103-1220 (March) 1932

Cutaneous Manifestations of Systemic Disease. U. J. Wile, Ann Arbor, Mich.—p. 1103.
*Malignant Thymoma of Reticulum-Cell Type with Pressure on Left Lung, Trachea, Esophagus, Left Phrenic and Left Recurrent Laryngeal Nerves, and with Metastases to Glands of Left Side of Neck; Importance of Biopsy for Differential Diagnosis of Cervical Lymphadenopathies. L F. Barker, Baltimore.—p. 1113.
*Management of Severe and Atypical Hyperthyroidism. F. H. Lahey, Boston.—p. 1123.
*Fallacies and Dangers in Treatment of Exophthalmic Goiter by Iodine. W. O. Thompson and Phebe K. Thompson, Chicago.—p. 1129.
Subacute Bacterial Endocarditis Following Extraction of Teeth: Report of Case. M. Bernstein, Philadelphia.—p. 1138.
*Management of Coronary Thrombosis and Its Complications. B. P. Seward, Roanoke, Va.—p. 1145.
*Paroxysmal Tachycardia Related to Menstrual Period. J. H. Crawford, L. H. Sigler and H. Fruchter, Brooklyn.—p. 1155.
Coincidental Occurrence of Diabetes Mellitus and Pernicious Anemia: Report of Two Cases. C Shookhoff, Brooklyn.—p. 1161.
Significance of Meningeal Permeability. S. Katzenelbogen, Baltimore.—p. 1168.
Use of Histamine Hydrochloric Acid as Test Meal. H. H. Haft, Syracuse, N. Y.—p. 1175.
San Francisco as Medical Center. W. J. Kerr, San Francisco.—p. 1178.

**Malignant Thymoma.**—Barker considers that in the case reported by him there is no indication for surgical intervention. Attempts to remove the intrathoracic tumor are unjustifiable. The risk from the operation itself would be very great, in the first place, and, in the second place, there is no probability that such surgical intervention would prolong life. Nor is there any advantage to be derived from removal of the lymph nodes of the neck, except for diagnostic purposes. The best therapeutic methods of intervention available are high voltage roentgen therapy and radium therapy. It is possible that one may be able to reduce the size of the mass within the thorax and also the size of the enlarged lymph nodes of the neck by such treatment. Of course, everything should be done, in addition, to build up the general health and strength of the patient by diet and by suitable hygiene. One must recognize, however, that any favorable results of therapy will be of but temporary duration.

**Management of Severe and Atypical Hyperthyroidism.**—Lahey believes that a large percentage of patients who are permitted to get into the advanced state of thyroid crisis will die. Their salvation is the early detection of an impending thyroid crisis or undue intensification of their hyperthyroidism and its emergency treatment with iodine, morphine, amytal, "avertin," salt solution and dextrose. By the early application of these measures, patients may be kept out of thyroid crises, prepared and operated on by subtotal thyroidectomy within three weeks, and definitely relieved of their thyroidism. Apathetic hyperthyroidism is a state characterized by signs and symptoms quite contrary to those of typical activated hyperthyroidism. It is misleading not only as to its existence but also as to its seriousness, and it possesses graver dangers of a fatality under stress or operative procedure than does the typical activated hyperthyroidism. An appreciation of its atypical signs and symptoms will result in its early diagnosis, and an appreciation of its certain unobtrusive seriousness should make one realize the possibilities of a fatality when the patient is submitted to any considerable extra burden, particularly such as subtotal thyroidectomy in one stage. It should make one undertake surgical procedures in all patients of this type, no matter how good they appear as risks, in two stages. Its earlier recognition and submission to surgery will result in a considerable lowering of its operative and nonoperative mortality rate.

**Dangers in Treatment of Exophthalmic Goiter by Iodine.**—The Thompsons call attention to the fact that since the introduction of iodine the mortality from thyroidectomy for exophthalmic goiter in the leading clinics has been lowered from about 1 to 4 per cent to about 0.25 to 0.7 per cent. This reduction is, they believe, less than is generally appreciated. The actual clinical improvement and reduction in basal metabolism caused by iodine is also somewhat less than is generally appreciated, owing to the fact that the influence of rest is usually not controlled. In very severe cases of the disease, operation should be performed as soon as the metabolism reaches a level during the administration of iodine, because the beneficial effects in such cases may be of short duration. In cases in which the basal metabolism is high after the prolonged administration of iodine and those in which the basal metabolism is rising rapidly during the administration of iodine, no operative procedures should be undertaken until iodine has been omitted long enough for the refractoriness to it to disappear (usually about four weeks) and then readministered. In the routine preoperative treatment of exophthalmic goiter it is desirable to give suddenly an adequate excess of iodine and not to precede this with small doses. A few patients still die from typical postoperative thyroid crises in spite of the administration of large doses of iodine. These reactions sometimes occur in patients who have shown satisfactory responses to iodine before operation. There is more to the treatment of exophthalmic goiter than the administration of iodine and the performance of a subtotal thyroidectomy. The skill of the surgeon, selection of the time and type of operation, proper attention to calories, protein and fluid in the preoperative and postoperative periods, abolition of fear and worry, and the type of anesthesia all seem to be factors of importance in keeping the mortality low.

**Management of Coronary Thrombosis and Its Complications.**—According to Seward, the rational treatment of coronary thrombosis depends on a knowledge of the anatomic changes that occur in the heart following thrombosis, and of the functional changes accompanying these. Morphine should be given in doses large enough and often enough to control the pain. Heat should be applied to the body of the patient. Stimulation with drugs should be avoided unless the heart sounds are very feeble and arrhythmic; the pulse is small in volume or imperceptible; the respirations are irregular and cyanosis is prominent. Caffeine sodiobenzoate should then be given in small rather than large doses, and it should be continued as long as the condition of the patient requires it. When nausea prevents the patient from taking an adequate amount of fluid and food, a small quantity of a concentrated solution of dextrose should be given intravenously, and saline and dextrose solution by rectum daily, and both should be continued until he can take a sufficient amount of fluids and food by mouth. Dextrose is readily utilized by all the body tissues, and the saline solution not only prevents dehydration but will increase the secretion of urine, which is especially desirable if the blood urea should rise to a high figure. When cerebral complications occur, the patient should be kept as quiet as possible; the clinician should continue to direct his attention chiefly to the heart and to the comfort of the patient. It is probably better not to give digitalis soon after coronary thrombosis occurs unless signs of heart failure appear. When the indications for it arise, it may be given in doses based on one-fourth to one-third minim per pound of body weight. If digitalis is given, it is better to discontinue it before the full therapeutic effect is obtained. Other therapeutic measures of great value are absolute rest in bed until the patient is well past the acute stage, good nursing care, and a diet consisting of easily digested and nutritious food. Laxatives should not be given until the patient is well along the road to recovery, but an enema should be given daily. The administration of oxygen may be helpful to those patients in whom cyanosis is a prominent feature. After the patient has recovered from the acute attack, the most important consideration is the supervision of his habits of life so that the heart may be spared any undue strain. When he may get up, how much activity he may be allowed, the use of digitalis and other drugs, his rest in bed each day and his general condition are questions that require much thought.

**Paroxysmal Tachycardia Related to Menstrual Period.**—Crawford and his associates report two cases of paroxysmal tachycardia of supraventricular origin, in one of which the attacks commenced at puberty and recurred at each subsequent menstrual period. In the other, the paroxysms commenced later in life. In the early stages they occurred at frequent intervals, but for a period of years they have almost invariably had a definite relation to the menstrual period.

*Electrosurgical Tonsillectomy: Advantages and Limitations of Fractional Electrocoagulation Method. A. R. Hollender, Chicago.—p. 216.

Bárány Noise Apparatus. B. M. Becker, Brooklyn.—p. 222.

Lateral Sinus Thrombosis: Review of One Hundred and Eighty-Four Cases, with Especial Reference to Postoperative Type. L. R. Boies, Minneapolis.—p. 227.

Congenital Bilateral Atresia of Nasopharynx: Report of Case. O. H. Peterson, Corpus Christi, Texas.—p. 238.

Intra-Oral Injuries and Infections of Pharyngeal Lobe of Parotid Gland. L. V. B. Spake, Kansas City, Kan.—p. 240.

**Etiology and Treatment of Tinnitus Aurium.**—Babbitt considers the syndrome of tinnitus aurium too complex to justify any conventional routine treatment. In the absence of cochlear degeneration or loss of function in the eighth nerve, the tympanic cavity offers a promising surgical field for the relief of tinnitus. The assumption of memory tinnitus without demonstrable labyrinthine or eighth nerve involvement is unwarranted.

**Early Intrinsic Cancer of Larynx.**—According to Tucker, early intrinsic cancer of the larynx will be recognized when the profession fully realizes the possible significance of chronic hoarseness. Biopsy by means of direct laryngoscopy should be the final step in the diagnostic study. Early "anterior intrinsic cancer" of the larynx is amenable to cure by laryngofissure, which will save the patient's larynx as well as his life, with no operative mortality. The anterior intrinsic group includes a large percentage of all cases of cancer of the larynx. Laryngectomy will cure practically all recurrences after laryngofissure if the cases are properly followed. In twenty-five of thirty cases reported by the author, more than a year has elapsed since laryngofissure. There have been two recurrences in two patients, giving a proportion of lasting cure of 92 per cent to September, 1931. One patient with recurrence is well, without metastasis, following laryngectomy. Partial laryngectomy with postoperative irradiation has given good results when there was a contraindication to laryngectomy in several cases not in the series. The author believes that laryngectomy will cure a large percentage of posterior intrinsic cancer if the diagnosis is made while the lesion is still recent.

**Physiology of Drainage of Nasal Mucus.**—Hilding calls attention to the fact that ciliary action and a protective, moving film of mucin over the surface are the chief mechanical factors involved in the drainage and defense of the nasal mucosa. The drainage, as activated by the cilia, is rapid, powerful and effective. Gravity plays a minor part. Traction, on the other hand, exerted on the film of mucin as on a net is an important factor in drainage. A complete exchange of the film of secretion over the surface takes place every ten or fifteen minutes in the more active regions in the nose, and about once an hour in the inactive regions. The drainage is directed backward with a strong tendency to flow toward the best protected areas; namely, the middle and inferior meatuses. The inactive anterior third of the nose drains largely through these meatuses by means of traction. The sinuses (as represented by the frontal sinus of the dog) have definite and extremely efficient drainage that is *spiral in direction*. With these points in mind, the necessity of changing the point of view of treatment of nasal conditions from an anatomic to a physiologic one becomes apparent.

**Reactions to Infection.**—Harkness states that the primary resistance to infections and foreign proteins is measured by the cellular reaction capacity. Secondary factors are certain substances, antibodies, in the humoral element of the blood that are themselves the product of the primary cellular reaction capacity. Cellular phagocytosis is the most effective weapon that the cell possesses in eliminating foreign protein material. A primary avidity for phagocytosis is retained not only by the leukocytic cells of the blood but by certain fixed tissue and wandering tissue cells. The reticulo-endothelial system probably includes the cellular elements responsible for the production of antibodies; it constitutes a hematopoietic system and embraces those fixed tissue cells and wandering connective tissue cells that have retained the greatest avidity for phagocytosis. Specificity of cellular reaction is the basis of *infection control and immunity*. It seems probable that, when the secret of specificity of cellular reaction is known, the major problems of immunity and infection will be solved. The so-called reticulo-endothelial system seems to offer the most fruitful field for the investigation of this problem, first, as the source of the humoral substances and the cellular elements of the blood that take an active part in combating infection, and, secondly, through possessing cells that seem to have powers of selectivity. The secret of cell specificity and selectivity in production and activity forms the crux of the problem.

**Allergic Nasal and Sinus Disease in Relation to Asthma.**—Baum is of the opinion that nasal and sinus disease is primarily not an etiologic factor in the causation of asthma. Asthma and nasal and sinus disease are often concomitant manifestations of the same condition in two different localities in the same patient, both dependent on the same underlying etiologic factors. Nasal and sinus operations should not be *performed primarily* for the cure of asthma, only such surgery being done as would be indicated by the same observations in the upper respiratory tract of the nonasthmatic patient. Allergic manifestations in the nose and sinuses should serve as warning finger posts, pointing the way to danger, and the patient should be so advised and should have his state of hypersensitization studied and treated—not only as a therapeutic measure directed to the cure of nasal symptoms but as a prophylactic measure calculated to prevent more serious consequences later.

**Rhythmic Movements of Palate, Pharynx and Larynx.**—Leshin reports that continuous synchronous rhythmic movements of the palate, pharynx and larynx are comparatively rare; only twenty-nine cases have been found in the literature. The review of these cases shows a definite relationship of these movements to organic disease of the central nervous system. No localizing neurologic significance can be ascribed to them as yet because of the varied pathologic changes found in the few postmortem examinations made.

**Electrosurgical Tonsillectomy.**—While diathermy for removing the tonsils has gained popular favor and has become the method of choice of some specialists, Hollender does not recommend its use as a substitute for surgery for the majority of cases. There are, however, definite advantages in an adequate substitute method when surgery is considered hazardous in the presence of certain systemic diseases. Since electrocoagulation of the tonsils is a scientifically sound method for selected cases, the specialist should familiarize himself with its technic.

*Cerebrospinal Fluid in Differential Diagnosis of Brain Tumor. F. Fremont-Smith, Boston.—p. 691.

**Progressive Facial Hemiatrophy.**—Archambault and Fromm state that progressive facial hemiatrophy is a well defined syndrome having distinctive clinical features, resulting from widely varying types of lesions, which apparently involve in selective fashion the sympathetic division of the vegetative nervous system at some point in either its central or its peripheral course. The condition is much more common than was formerly believed, may develop at any period of life, and exhibits no material predilection for the female sex or for the left side, as was maintained by classic authors. The actual etiology of facial hemiatrophy still remains largely speculative, but it is believed that in many cases immediately antecedent infections and faciocervical traumas are an actual causative factor. Aside from its undeniably close relationship to scleroderma, which itself may be responsible for some cases, the various theories advanced to provide a logical pathogenesis, with the exception of the sympathetic theory, are believed to be totally untenable. Three cases of typical facial hemiatrophy are presented in detail, and all three exhibited unescapable evidence of disturbances in the domain of the cervical sympathetic system.

**Chronic Progressive Vascular Subcortical Encephalopathy.**—Farnell and Globus describe a case of Binswanger's chronic progressive encephalitis. It differs from the typical case in that it occurred in a somewhat younger person, ran a rather rapid clinical course, and manifested decerebrate rigidity as a striking atypical feature. The latter may find explanation in the degenerative changes noted in the substantia nigra. The disease is degenerative; Binswanger, though recognizing it as such, erred in choosing the term encephalitis. Instead, the term chronic progressive vascular subcortical encephalopathy is suggested as more descriptive of the lesion and of its possible etiology. The disease presents no clearly distinguishable clinical diagnostic features but merits consideration in the differential diagnosis of atypical instances of cerebral arteriosclerosis.

**Histologic Changes in Brain in Cases of Fatal Injury to Head.**—In studying histologic changes in the human brain consequent to injury, Rand and Courville utilized the newer metallic methods, as well as routine stains. In this contribution they limit themselves to a consideration of the microglia and oligodendroglia. The history of these two elements is briefly traced, with especial reference to more recent studies with specific metallic methods. To the present time the reaction of these elements to injury has been critically studied only in experimental animals. The authors attempt to follow the changes in the microglia and oligodendroglia in cases of fatal injuries to the human brain. They selected twenty-four cases from a larger series which represent fairly typically the sequence of changes occurring in edema, contusion and laceration, and gross and petechial hemorrhages of the brain. It was found that the microglia react to local destruction and disintegration of tissue. The oligodendroglia, on the contrary, are altered in response to general or widespread processes, particularly edema. Transitional forms of microglia were found within the first few hours following contusion or laceration of the brain. Compound granular corpuscles, however, were found only after three or four days and remained as long as the products of disintegration were present. Typical transitional stages could be traced from normal microglia to fully developed phagocytes. The oligodendroglia became enlarged and vacuolated almost immediately following injury. Within a few hours, typical widespread acute swelling of the cells was present. This reaction undoubtedly persists for weeks, especially in the region about local injuries. Both types of cells undergo destruction along with the nerve cells and neuroglia, at the margin of lacerations and in severely contused areas. Evidences of direct cell division were observed in both types of cells within a few hours after injury, and it was especially active during the first few days. Mitosis was found only in fully developed compound granular corpuscles. Changes in the astrocytes and nerve cells will be described in later communications.

**Familial Progressive Muscular Atrophy.**—Moleen presents a case of a symmetrical type of muscular atrophy, chronic and progressive in course, which had been under observation for over twenty years. Three brothers were subjects of the same disease; one died without the condition having been studied pathologically; one forms the basis of the author's study; the third is still living at the time of the report, in an advanced state of the disease. The absence of group muscular involvement referable to the enlargements of the cord is noteworthy in all three cases. The marked changes in the voluntary muscles reached a degree of almost complete disappearance of the fibers without evidence of inflammatory reaction. The negligible involvement of the spinal gray matter and the apparently normal functioning condition of the polar cells is remarkable if not unique. Noninflammatory degeneration of the myelinated elements of the peripheral nerves appears to constitute the primary pathologic lesion. The suspicion expressed with reference to the possible primary structural defect is strengthened by the familial incidence.

**Cerebrospinal Fluid in Differential Diagnosis of Brain Tumor.**—According to Fremont-Smith, a false low cerebrospinal fluid pressure may be caused either by dehydration due to catharsis, diarrhea or excessive vomiting, or by obstruction to free communication between the lumbar manometer and the ventricular fluid. Jugular compression should always be performed to test this communication, which may be completely or partially interrupted by a nerve root obstructing the tip of the needle, by a spinal subarachnoid block due to a spinal cord tumor, adhesive meningitis, and so on, or by a tumor of the posterior fossa or the third ventricle. If jugular compression fails to give a prompt rise in the lumbar manometer, abdominal compression should be tried. If abdominal compression fails to give a prompt rise, the needle is not properly in place or is obstructed by a nerve root. Prompt response to abdominal compression gives assurance that the lumbar manometer communicates freely with the lumbar fluid. When the spinal subarachnoid space is blocked by a tumor, Pott's disease or adhesions, abdominal compression gives a more prompt and more marked rise in the lumbar manometer than does the jugular compression. A brain tumor nearly always causes increased cerebrospinal fluid pressure unless the patient has been dehydrated. The pressure is often elevated for several months before the disks become choked. Very early tumors, infiltrating gliomas of the pons and pituitary tumors that remain within the sella turcica may give normal cerebrospinal fluid pressure. The author presents in tabular form the cytologic and chemical changes that occur in the cerebrospinal fluid in brain tumor and in various other pathologic conditions of the brain and spinal cord.

*Local Anesthesia in Tonsillectomy. H. A. Trotter, Buffalo.—p. 435.

**Intracranial Complications of Otitic Origin.**—Friesner and Druss call attention to the frequency with which disease extending from the middle ear and mastoid becomes localized about the posterosuperior portion of the pyramid. A bone focus at this site may develop a brain abscess in either the posterior or the middle fossa or a meningitis. The otologic surgeon must be equipped as a cranial surgeon as well. The authors believe that, with a technic such as Eagleton has described, these foci may be exposed. Furthermore, the question is again raised whether exploration of the brain might not be attended with better results if it were made through such an exposure.

**Histopathologic Reactions of Tracheotomic Wound.**—According to Richards and Glenn, simple incisions in the trachea, if not infected, tend to heal with great rapidity. The defect is closed by a connective tissue growth, without any evidence of true regeneration of cartilage. The mucous membrane between heals rapidly, though with a modified type of epithelium. There is little if any tendency for encroachment on the tracheal lumen by the healing tissues in this type of wound. The presence of a tracheal cannula delays the healing of the wound and increases the amount of connective tissue formed about it. So long as there is an adequate opening in the trachea for the cannula and no pressure against the cartilaginous edges, there is very little tendency toward the formation of granulations large enough to cause any appreciable obstruction to the tracheal lumen. Infection about the cannula, occasioned primarily by too close approximation of the wound edges about it, increases the tendency to connective tissue formation. With a large anterior tracheal defect there is little tendency for the superficial tissues to fall in and encroach on the lumen of the trachea. With a tracheal fistula, in the absence of a tube, the wound tends to close rapidly without any impairment of the tracheal lumen.

**Local Anesthesia in Tonsillectomy.**—In performing tonsillectomy, Trotter has used quinine and urea hydrochloride solution, 1 per cent in strength, 2.5 cc. to each tonsil. Ten minutes is allowed for full anesthesia. In 500 cases, nerve block anesthesia with quinine and urea hydrochloride proved satisfactory. The author has not experienced any complications or ill effects from either quinine and urea hydrochloride or epinephrine hydrochloride. The anesthesia at the time of operation is excellent, and the recovery of the patient is much smoother because the anesthesia lasts for several days.

**Endocrine Treatment of Paget's Disease.**—According to Berman, Paget's disease is an entity representing a disturbance of bone metabolism involving an imbalance between the parathyroids and the suprarenals, there being excessive function of the former and deficient function of the latter. In sixteen out of eighteen cases, the regular administration of suprarenal cortex hormone with a high calcium diet produced a relief of the pains in the extremities and the head, a restoration of the sense of health and well being with a return to occupational activity, and an apparent arrest of the disease as shown by the cessation of development of deformity and the symptoms of sympathetic nervous system irritability. The course of Paget's disease is chronically protracted; in general, its progress is downward. The results of the cases reported, although they are limited in number and have still to be checked and watched, justify the conclusion that suprarenal cortex hormone is a valuable remedy for a disease which has heretofore had no remedy.

**Hyperpituitarism Beginning in Infancy.** — Behrens and Barr report a case of preadolescent gigantism of pituitary origin in a youth, aged 13. An extraordinary feature was the beginning of abnormal development in early infancy. Growth has been steady without spurts during the entire period of childhood and has continued at an undiminished rate during nineteen months of observation. Of special interest is the low basal metabolic rate accompanied by subnormal temperature and cold hands and feet. Remarkable, also, is the extraordinary size of the mastoid cells and the pneumatization of the squamous portion of the temporal bone.

**Specific Action of Anterior Pituitary.**—Loeb states that samples of anterior pituitary substance from different species of mammals as well as of urine of pregnant women differ from one another in their effects on the genital organs and thyroid of immature guinea-pigs; these effects in the case of each species are specific. He discusses the possible interpretations of these observations, which are more readily compatible with the view that at least two constituents of the anterior pituitary are responsible for these effects than that the latter are attributable to the action of different quantities of one and the same substance, and that in these different species these two substances are distributed in different proportions. In the guinea-pig only guinea-pig anterior pituitary seems as a rule to be able to induce ovulation. The author recognized intermediate states of proliferation of the vagina which occur under the influence of large growing or mature follicles under certain conditions; there is some indication that the interstitial gland and theca interna lutein bodies, if present in sufficient quantity, may exert functions similar to that of the corpus luteum and, under certain conditions, inhibit ovulation and full proliferation of the vagina.

**Quinine and Iodine in Exophthalmic Goiter.**—Bram calls attention to the fact that persons with exophthalmic goiter are relatively insusceptible to cinchonism and can take quinine in doses of from 30 to 90 grains (2 to 6 Gm.) daily with impunity and often with benefit. This is the basis of the quinine test for hyperthyroidism especially when associated with exophthalmic goiter, and is again recommended as a safe, simple and dependable diagnostic procedure. The effects of quinine in exophthalmic goiter resemble, in many respects, those of iodine. Following its use there occurs in the average case an amelioration of the symptomatology of the syndrome. Quinine in large doses is a valuable asset in the armamentarium of the internist who has sufficient experience with subjects of exophthalmic goiter to realize the complex needs of these patients. It must be emphasized that quinine is not the mainstay but is a valuable asset in the broad regimen of therapy which must include attention to discoverable etiologic factors, diet, psychotherapy and proper environment. Quinine differs from iodine administration in exophthalmic goiter in the following respects: (1) Quinine can be given for an indefinite period of time without danger of flaring up of symptoms; (2) it does not produce the marked increase in size of the thyroid that often occurs after iodine administration, and (3) while the beneficial effects of quinine are slower in appearing than those of iodine, the results are continuous and cumulative. Quinine and iodine may complement each other in treatment. Also, quinine in proper dosage given in combination with iodine in small doses appears in the average case to serve as a deterrent to the classic rise in symptoms following prolonged iodine administration. When recovery is reached, the singular tolerance to large doses of quinine gives way to normal susceptibility to cinchonism.

**Suprarenal Hemorrhage in the New-Born.**—Goldzieher and Gordon believe that an intra vitam diagnosis of suprarenal hemorrhage in the new-born may be made on the basis of a definite syndrome. This consists of two groups of symptoms: those due to acute suprarenal insufficiency and those produced by internal hemorrhage. Either one of these may predominate. Symptoms of acute insufficiency consist of acute onset, high temperature, rapid respirations, petechial or purpuric rash, cyanosis and metabolic changes—especially hypoglycemia. Associated with these are gastro-intestinal and nervous disturbances. These may be accompanied or masked by signs of internal hemorrhage (shock, collapse, weak pulse) and local signs of abdominal distress, distention and the presence of a mass in one or both kidney regions. Five cases are reported in which an intra vitam diagnosis was made of suprarenal hemorrhage in the new-born. On the basis of the syndrome presented in these cases, an analysis is made of eighty-one cases of the condition both in the new-born and in infants. The treatment suggested by the authors consists of intravenous transfusion of blood, injections of dextrose, and the administration of a potent suprarenal cortical extract.

**Glycopenia.**—Shepardson reviews the various causative factors, besides hyperinsulinism, producing glycopenia. He reports two cases in which the hypoglycemia apparently resulted from primary hyperinsulinism. It is suggested, in contrast to the usual increase in carbohydrate intake, that the diet be markedly reduced in carbohydrates and that a relatively high fat diet be substituted, in the treatment of essential glycopenia. Results in the cases reported indicate that such alteration of the dietary formula apparently has an inhibiting influence on the incretory function of the pancreas.

**Influence of Ligation of Pancreatic Ducts of Dogs on Serum Amylase.**—Johnson and Wies demonstrated a sharp contrast in regard to the postoperative amylase concentration of the serums of dogs, depending on whether ligation of the pancreatic ducts was or was not a part of an otherwise prescribed operation. The characteristic feature is a marked rise of several hundred per cent in serum amylase concentration, sustained for several days, which is observed when the pancreatic ducts have been ligated.

**Cultivation of Typhus Fever Rickettsia in Presence of Live Tissue.**—According to Nigg and Landsteiner, Rickettsia prowazeki can be cultivated for many generations in vitro, without diminution in numbers or virulence, in mediums similar to those described by Maitland, Rivers and others for the cultivation of certain viruses. In all probability, such cultures can be maintained indefinitely. It has been impossible, thus far, to cultivate the typhus rickettsia without employing living tissue.

**Reaction of Rabbits to Streptococci.**—Schultz and Swift rendered rabbits very hypersensitive by relatively small doses of green streptococci given intracutaneously, and somewhat less hypersensitive by similar doses of heat-killed vaccine prepared from hemolytic streptococci. Animals receiving the same doses intravenously gave, on subsequent testing, lesions slightly more marked than normal controls; but these lesions were qualitatively hard and nodular compared with the large edematous lesions in the cutaneously sensitized group. There was no parallelism between the degree of cutaneous or ophthalmic hypersensitivity and agglutinin titer in the blood serum. The authors believe that bacterial hypersensitivity to whole streptococci depends more on previously induced focal infection than on circulating antibodies.

**Tolerance for Mercury Poisoning Increased by Frequent Hemoglobin Injections.**—Havill and his associates report that frequent injections of superthreshold amounts of dog hemoglobin will cause deposits of pigment material in the renal tubular epithelium. When this has happened, the dog will survive minimal lethal doses of mercuric chloride with little evidence of renal injury. In fact, some dogs will tolerate twice the minimal lethal dose without severe reaction. There is no evidence that continued injections of dog hemoglobin in these amounts will cause any injury or functional disability of the kidney. Rest periods will effect a disappearance of this pigment in the renal tubules.

**Vaccines in Clinical Medicine.**—Keilty considers that the position of vaccines, theoretically, experimentally and clinically, is today one of imbalance. There has been too much accomplished in the past to disregard them entirely, and a middle ground is an acceptable attitude. A vaccine is defined as a vaccinogenic solution having the power of producing specific antibodies in vivo. Vaccines prepared from a multiple flora are selected by the author exclusively on their quantitative appearance in culture and their allergic cutaneous reactions. Vaccines must start out with the study and isolation of specific etiologic organisms. They must be prepared in such a way that the vaccinogenic factor is as nearly unaltered as possible, but no solution should be used in which a viable organism has any chance of becoming virulent. The present trend in dosage is to start with small amounts, 0.1 cc., increased in 0.1 cc. stages and given every other day over a long period. Each individual case is an entity and for this reason the best results are obtained after experience. In the preparation of a vaccine, one should pay no attention to the bacterial count but make heavy suspensions and vary the dosage according to general reactions. The desirability of general reactions for immunity producing purposes is stressed.

**Bacteriology of Pus.**—Norton emphasizes the fact that the proper collection of material is essential for a satisfactory laboratory examination. Skin contaminants must be rigidly excluded. Too great emphasis cannot be placed on this point, if the laboratory worker is to give the clinician a true picture of the bacteriology of the material submitted. The first step in laboratory examination of pus is, under all conditions, the preparation and examination of a proper smear on a microscope slide. Care should be taken to make thin film preparations. A stain according to Gram's method gives the most valuable indication of any single stain but will not, of course, detect the tubercle bacillus. Hence it is extremely desirable for the laboratory to be furnished with accurate information concerning the source of the material. Various modifications of the original Gram method have been introduced. The author's experience has been that careful attention to the details of the technic is fully as valuable in yielding consistent results as any modification of the solutions employed. This is particularly true in regard to the alcohol (or acetone) decolorization. In "old" pus the Gram stain may be uncertain. In many laboratories, the methylthionine chloride stain is used for the detection of gonococci. While this is reasonable under special conditions in which the clinician and the laboratory work in close cooperation, it is not to be recommended. Furthermore, it is highly desirable to make a Gram stain if organisms resembling the gonococci are seen in the material submitted, so little is gained by the use of methylthionine chloride. For pus from tuberculous conditions, the Ziehl-Neelsen method, or some of its modifications, is in general use. The methylthionine chloride stain may be used for detecting organisms resembling diphtheria bacilli, while either methylthionine chloride or gentian violet is useful for staining the spirochetes and fusiform bacilli characteristic of Vincent's infection.

**Bacteriology of Nose and Throat.**—Noble and Brainard call attention to the fact that many bacterial species are to be found in the nasal passages and throat, and that the same or apparently the same species occur on both the healthy and diseased mucous membrane. Therefore it is difficult, in the absence of a definite lesion, to appraise satisfactorily the clinical significance of many of the species encountered in a bacteriologic examination. This is especially true of the streptococci, whether green, indifferent or hemolytic, the pneumococci, staphylococci gram-negative cocci and hemoglobinophilic bacilli. If one considers the hemolytic streptococci as an example, one must remember that they constitute a large group of many strains which differ greatly in their pathogenicity and virulence, and that while certain strains may give rise to scarlet fever or to septic sore throat, others may be innocuous. The finding of hemolytic streptococci, therefore, is not necessarily significant, but the finding of a particular strain may be of great significance. Unfortunately, the demonstration of a particular pathogenic strain is not always easy and usually is not practical in routine examinations. The rôle of the anaerobic bacteria as incitants of colds and influenza is unknown; they would appear to be part of the normal flora and of little if any pathogenicity, but additional experimental evidence may change these views. Recent work has again directed attention to the probability that a filtrable virus is the primary cause of certain respiratory infections, preparing the way for the secondary complications, which may be brought about by many of the common bacteria harbored in the upper respiratory tract.

**Laboratory Methods in Treatment of Pneumonia.**—Plummer states that, during the past few years, pneumonia has been the subject of extensive investigation, but most of the discoveries have not yet reached the stage of practical significance. Perhaps the most important advance toward the solution of this problem has been the chemical fractionation of the pneumococcus. This information has recently been applied by Avery and Dubos to the development of an enzyme that splits the carbohydrate fraction of the type III pneumococcus and by so doing destroys the toxicity of this organism. Already these scientists have been able to protect mice against the type III pneumococcus infection, and it is probable that this agent will be of value in the treatment of pneumonia. The majority of pneumonia patients today are not given the benefit of typing, even when the advantages of type diagnosis are so striking, as shown by the following example: Two pneumonia patients with the same amount of lung involvement and the same degree of toxemia are seen late in their infection. Assume that one is a type I with a negative blood culture and the other a type III with a positive blood culture. The type III patient will almost certainly die, the type I has a good prognosis, and, if given the benefit of an efficient therapeutic agent, such as concentrated serum, will almost certainly recover. In the up-to-date management of pneumonia, the sputum should be carefully examined and rapidly typed as a guide to prognosis and to insure the prompt administration of serum in types in which it has been found efficacious. Blood cultures and other laboratory procedures should be instituted in order to recognize early the presence of septicemia and other complications. In short, it is evident that the modern treatment of pneumonia is dependent on the utilization of the latest bacteriologic and immunologic methods.

**Primary Ileostomy in Treatment of Generalized Peritonitis.**—Baumgarten states that patients with generalized peritonitis of appendiceal origin should be treated as cases of intestinal obstruction. Intestinal drainage is paramount in the treatment of these patients. Primary ileostomy is a satisfactory means of securing intestinal drainage, controlling dehydration and the acid-alkali balance of the blood plasma. Persistent fecal fistula is not a common complication. Nineteen cases of generalized peritonitis following appendicitis are reported by the author with three deaths, or a mortality rate of 15.7 per cent.

**Craniocerebral Injuries.**—Risley discusses the question of the element of danger in doing spinal tap in acute cases of craniocerebral injury, for the emergency within the skull is so great, because of the rapid accumulation of fluid within its closed walls, that permanent cerebral damage is quickly accomplished unless this rapidly accumulating fluid is speedily removed. Edema and hemorrhage, accompanying the more severe grades of brain injury, immediately result in the interference with absorption of cerebrospinal fluid by the normal paths, and a vicious circle is set up, which causes further pressure on the brain and a resulting cerebral anemia. This anemia, if not relieved at once, leads with great rapidity to gliosis and lasting changes in the cerebral tissues, which, in turn, effect permanent changes in the disposition, character and mentality of the patient. Relief of this tension is therefore essential and should be brought about without delay. It is best accomplished by repeated spinal taps. It has further been demonstrated that this procedure, if carried out as a routine, will in the vast majority of cases obviate the necessity of later decompression operations. This measure is especially applicable to cases of fracture of the base of the skull. The picture in the more severe types of fractured base is rarely clean cut, and, unless one is able to get an absolute confirmation by roentgen examination, one is liable to have a confused and ill defined picture presented and can make a diagnosis only by a process of elimination. If, however, one estimates the extent of cerebral damage by a measurement of intracranial pressure, one can obtain a much more clearly defined picture, and the treatment can be worked out much more logically. The author emphasizes the fact that the important consideration, in all types of head injury, is the prevention of cerebral damage. This is to be accomplished by efforts to keep the intracranial pressure as nearly normal as possible.

**"Avertin" as Basal Anesthetic.**—Marvin believes that "avertin" should be used only as a basal anesthetic. It should be given only by a well trained anesthetist or under his direction. Every detail of technic should be executed accurately. Carelessness will be penalized by morbidity and mortality. It causes a peaceful, quiet and rather rapid induction with early relaxation. The amount of ether or nitrous oxide used as an adjunct is greatly reduced. It should be used alone, and not in combination with other drugs whose synergistic action might produce serious complications.

**Focal Infection as Factor in Heart Disease.**—In studying some problems in dental focal infection, Haden injected 1,500 rabbits intravenously with bacteria from periapical infection. The organisms were principally nonhemolytic streptococci. Each animal received 5 cc. of a twenty-four-hour broth culture and was examined post mortem in from three to six days. The organisms were grown under partial oxygen tension, a point most important in preserving pathogenicity during the period intervening between removal of the bacteria from the body and their injection into the experimental animal. All gross lesions observed at the routine necropsy were tabulated. In this series, 18 per cent showed gross endocardial lesions and 10 per cent showed lesions in the myocardium. The lesions recorded are only those which were visible to the naked eye. If microscopic studies had been made, the incidence of lesions in the myocardium would certainly have been much higher. The myocardial lesions observed were hemorrhage, sometimes limited to the right auricle, areas of necrosis of the heart muscle, and occasionally small abscesses. It seems apparent from such results that the organisms in chronic septic foci are well able to produce disease of the myocardium and heart valves. The important lesson to be learned from a study such as this is the realization on the part of the clinician of the potential danger to the heart of chronic septic foci. If this is kept in mind, the importance of removal of focal infection early instead of late is apparent. There seems to be no doubt that the judicious removal of septic foci will do much to lessen the incidence of heart disease, especially of the myocardium. In patients in whom the heart valves are already damaged by the rheumatic virus, the removal of foci of infection should lessen also the incidence of subacute bacterial endocarditis. Early removal of chronic foci in all diseases of focal origin cannot be stressed too strongly. Too often the late removal is disappointing and the importance of chronic foci is underestimated because the systemic disease, although of focal origin, is beyond repair. Systemic disease of focal origin should be cured before it develops.

**Eczema in Infancy and Childhood.**—According to Bivings, most infantile eczemas are allergic in origin. Prompt and lasting relief can usually be obtained by thorough testing and the elimination of offending foods. The phenomenon of immunity will result in recovery, without treatment, in the mild cases and in the more severe also, but a long period of suffering can be eliminated if the cause is determined and removed. Cow's milk, eggs and wheat are the most common offenders, but many errors and failures will result if they are the only factors considered. Local treatment, combined with testing and elimination, is probably the method to be recommended.

**Herpetic Fever with Stomatitis.**—Youmans reports a case of idiopathic herpetic fever with stomatitis, in which the virus was isolated from lesions of the mouth. Attempts to isolate the virus from the blood and spinal fluid failed. The author discusses the significance of the clinical features and laboratory studies with respect to the pathogenesis of herpetic fever.

**Solitary Cysts of Kidney.**—McKay believes that Hepler's explanation that solitary cysts of the kidney are the results of urinary obstruction to part of the kidney parenchyma plus interference with the blood supply is the most logical theory that has been advanced. A plain roentgenogram with the colon cleared of gas will usually show the outline of the cyst. Pyelograms may vary. They are usually confused with renal neoplasms. All solitary cysts of the kidney should be operated on. The serous cysts should be resected when sufficient renal parenchyma remains. In all solitary cysts of the kidney that are hemorrhagic, however, a nephrectomy should be done.

**End-Results of Treatment for Peptic Ulcer.**—Contrary to the practice of many clinicians, Morgan does not employ alkalis to any great extent in the treatment of peptic ulcer, using only magnesium oxide. Early in his practice he formed the opinion that soda in any form administered in peptic ulcer cases not only did little good but often seemed to retard healing. This experience gained in the early years of his practice has become a settled conviction after years of extensive experience with this type of digestive disorder. From his own experience of thirty-five years in dealing with peptic ulcer, and from an exhaustive study of the literature bearing on this subject, he is convinced that individuals who have been cured of the subjective and objective symptoms of peptic ulcer, and have been free from symptoms for a period of five years, have not only as favorable a life expectancy, but are as comprehensively unimpaired for the carrying on of their accustomed vocation, as any similar group who have suffered any other serious illness.

*Statistical Study of Acute Appendicitis. L. W. Jordan, Portland, Ore.—p. 201.

**Bowel Distention.**—Gatch and his associates describe experiments which indicate that the factors which govern the absorption of the toxic material from the intestine are more important than those which govern its formation. They favor the opinion that this absorption is mostly transperitoneal and that the peritoneum has considerable ability to hinder it. They lend support to the view that the best treatment of advanced ileus is simple relief of obstruction. The ability of seminecrotic bowel to recover is phenomenal. The authors' experiments show that a rapid drop in blood pressure is the most constant indication that absorption of toxic material has occurred. They believe that this makes spinal anesthesia dangerous.

**Statistical Study of Acute Appendicitis.**—Jordan studied a series of 587 cases of acute appendicitis. Of this number, 30, or 5.11 per cent, ended fatally. Only those surgical cases were considered in which there was a pathologic diagnosis of acute appendicitis. During the acute attack, previous to their entrance to the hospitals, many of the patients had had laxatives and enemas. In this series of cases, the average clinical picture of acute appendicitis was determined. In comparing the nonfatal cases with the fatal cases, the differences between the symptoms, physical signs and laboratory observations in the two groups were not great enough to be of much practical significance in determining the prognosis. Delay in surgical treatment was found to increase the death rate, which was 5.11 per cent.

Spas and Spa Treatment in Europe. M. B. Ray.—p. 253.

**Diathermy of Brain.**—Kowarschik states that there are two ways of diathermizing the brain. The first is the transverse method. Here one uses two small lead electrodes (5 by 5 cm.) placed on both temples, and fastened with a bandage. The second method is by sending the current through the head in a sagittal direction. One electrode (4 by 12 cm.) is placed on the forehead, above the eyebrows; the other (of the same size) on the back of the head, at the hair border, or even on the hair, if this is well wetted with soap and water. The sagittal diathermizing of the brain will warm up the frontal lobes, the midbrain, the pons, the medulla oblongata and the cerebellum. With both methods the current should be strong enough to produce only a mild and agreeable feeling of warmth; in most cases from 0.2 to 0.3 ampere will suffice. Stronger currents will sometimes cause dizziness or headaches. To avoid dizziness, it is best to have the patient recumbent during the treatment, which should not be longer than about fifteen or twenty minutes—though some recommend as long as an hour. By the use of either method one can diathermize the brain, producing a hyperemia and so improving the functions of the brain centers. These respond frequently to diathermy. One notes a decrease of blood pressure in cases of hypertonia, a regaining of consciousness with uremia, an increase of urine in many persons, an increase of basal metabolism, and an effect on the activity of the generative glands. The author believes that in the past these many effects of cerebral diathermy have been used far too little in therapeutics and strongly recommends their more frequent use—the more so since diathermy is entirely free from danger.

**Elimination of Uric Acid.**—Comel states that, following thermal mud-packs, great amounts of uric acid are excreted through the skin. A drainage of uric acid from tissues admittedly occurs, as the elimination of uric acid is very high even with a purine-free diet, and is particularly high in persons with gout and those showing hyperuricemic arthritis.

**Iodized Poppy-Seed Oil in Diagnosis of Intrathoracic Disease.**—Burrell reviews the various methods of administering iodized poppy-seed oil 40 per cent. There are disadvantages in the cricothyroid method. If it is not given properly, the material, instead of being injected into the trachea, goes into the surrounding tissues and may lead to cellulitis and a considerable amount of pain, if not actual danger. Introduction by the nasal route is simple, but there is a possibility of laryngeal spasm. The usual method of introduction at present is through the cords with a laryngeal syringe. The most obvious indication for the use of the oil is bronchiectasis, in which condition it is a guide to treatment, which depends largely on whether the disease is unilateral or bilateral. The author has frequently had a patient with obvious signs of bronchiectasis in one lung, and only by the use of the oil has he discovered that there was considerable bronchiectatic dilatation on the other side. Before urging a surgical operation of any magnitude, therefore, it is essential to have a roentgen examination after using the oil. Again, it is difficult or impossible to determine clinically the extent of the bronchiectasis, and treatment depends largely on extent. If bronchiectasis is confined to the extreme lower lobe of the lung, it is possible to have that lobe excised. The author has been most impressed by the results of operation. It was not until iodized poppy-seed oil 40 per cent was introduced that one recognized that a certain proportion of cases of unexplained hemoptysis were really bronchiectasis. Formerly such patients would be sent to a sanatorium, but now it is possible to clinch the diagnosis in many cases. Every case of unexplained hemoptysis should be examined by roentgen rays after injection of the oil.

**Radiation Treatment of Leukemia.**—Horder reports that roentgen rays applied to the left upper abdomen have great value in both myelocytic and lymphatic leukemia. They probably prolong life in most cases and they certainly make the patient much more comfortable. Radiations must be used carefully, but in sufficient doses. The tendency at present is to underdose. On the other hand, great care must be exercised at the beginning of the treatment. The state of the red cells and hemoglobin must be taken into account in controlling dosage. They have, in fact, even greater importance than the white cells.

*Conservative Mastoidectomy for Chronic Suppurative Otitis Media. L. G. Brown.—p. 470.

**Blood Sedimentation Rate in Pulmonary Tuberculosis.**—Roche considers that the blood sedimentation rate is of proved value in the management of cases of pulmonary tuberculosis. The technic is simple. Readings at the end of the first hour are usually sufficient. Regular and repeated estimations are essential. The author strongly urges that the information provided by such estimations should be carefully considered when prescribing rest and exercise, particularly in patients whose temperatures and pulse rates are within normal limits. It is his opinion that attention to this point will tend to minimize the risk of relapse.

**Conservative Mastoidectomy for Chronic Suppurative Otitis Media.**—Brown calls attention to the fact that chronic suppurative otitis media (in reality, chronic mastoid disease) still remains far too prevalent in spite of its admitted dangers to the patient and the loss of national efficiency due to deafness. Conservative mastoidectomy, though devised and advocated as long ago as 1907 by Charles Heath, has not yet gained the universal support it deserves. The author advocates a modification of Heath's operation, termed "transantral attico-tympanotomy," and describes the results he obtained in a series of cases.

### Glasgow Medical Journal

**36:** 113-168 (March) 1932

*Convulsions in Infancy: Part I. S. Graham.—p. 113.
Id.: Part II. N. Morris.—p. 126.
*Id.: Part III. J. B. Rennie.—p. 133.

**Convulsions in Infancy.**—Graham stresses the great value of chloral hydrate in convulsions in infancy (2 to 4 grains, or 0.013 to 0.026 Gm.) by mouth, or, if the patient is unable to swallow, 5 grains (0.03 Gm.) dissolved in a little water and given by rectum. The action is rapid and very effective and obviously more lasting than chloroform. Indeed, in the idiopathic type of convulsion, chloral hydrate given in this way and repeated every two hours if necessary (1 grain, or 0.0065 Gm.) to an infant 1 month of age is a most satisfactory form of treatment. The chloral hydrate should not be stopped when the convulsions cease, but the dose must be reduced gradually and the interval lengthened until the daily amount given is very small. This gradual reduction of the chloral over a period of several days is most important. Having controlled the attack, it is necessary for rational treatment to ascertain if possible the cause. Fever is usually present, not as effect but as cause, and usually indicates some infection. The discovery of an early bronchopneumonia or an otitis media, for example, renders the most probable cause of the convulsion tetany. The facial phenomenon will be absent after the convulsion, and probably none of the other signs of tetany will be present, but this does not invalidate such a diagnosis of tetany. The most difficult task is the decision regarding the presence or absence of disease of the nervous system, especially meningitis. A bulging fontanel always demands a lumbar puncture as a therapeutic as well as a diagnostic measure, although the results of lumbar puncture as a means of controlling the attacks are particularly disappointing. If a diagnosis of tetany has been arrived at, treatment with calcium chloride and cod liver oil (or one of its substitutes) should be instituted. Terminal convulsions, such as occur so commonly in tuberculous meningitis and less commonly in pneumonias and other similar infections, are best combated by chloral hydrate. Morphine may be used, but it is less safe and less efficient, while the bromides are perfectly safe but still not as efficient. Generally speaking, in all cases the bowels should be attended to. The dose of castor oil, or, if in a hospital, the rectal wash-out, will be helpful in any event at the onset of an infection, but when this has been done properly it is not necessary and may be distinctly harmful to repeat the procedure. The continued use of such drugs as mercury with chalk under these circumstances is unwarranted.

**Blood Changes in Convulsions in Infancy.**—According to Rennie, the total serum calcium and diffusible calcium are reduced not only in cases with clinical signs of tetany but in many cases of convulsions with no other evidence of tetany. The serum protein influences only the protein-bound calcium, which is inert as regards neuromuscular excitability. The injection of amino-acids intravenously in animals causes a definite fall in the serum calcium. From these results it seems fair to conclude that the products of protein decomposition, certainly those in the form of amino-acids, can combine with calcium, remove it from the serum, and thus induce hypocalcemia. It may be, therefore, that the presence of excess amino-acids in many conditions causes low serum calcium and convulsions.

*Experimental Error in Enumeration of Leukocytes and Its Application to Hemoclastic Crisis. Irene Yates and J. C. Batt.—p. 160.

**Syphilis in Mental Hospital Practice.**—Nicole and Fitzgerald did the micro-Meinicke clarification reaction in 1,350 mental cases, 175 of these being selected for comparison with other tests, these others being the macro-Meinicke clarification reaction, the original Sachs-Georgi test, the Sachs-Witebsky test and the Wassermann test, performed on an average five at a time on each serum. Cerebrospinal fluid was tested in 170 of these cases by means of an average of four of these reactions and also by six usual chemical tests. The cases included 53 nonsyphilitic persons, 38 syphilitic persons (without dementia paralytica), of which 17 had been treated, 26 dementia paralytica patients before treatment and 58 after malaria. Disagreements between these tests occurred (in blood) in 36 cases, of which 4 were nonsyphilitic, 5 untreated syphilitic persons, and 27 treated (including dementia paralytica). Noteworthy points were: 1. The micro-Meinicke clarification reaction and the macro-Meinicke clarification reaction were only once wrongly negative. 2. The Sachs-Witebsky was never wrongly positive, and was more sensitive than the original Sachs-Georgi, but not more sensitive than the Wassermann. 3. The Meinicke clarification reactions were superior to all others in sensitivity. A routine procedure is suggested, consisting of applying a micro-Meinicke clarification reaction to all patients on admission, and testing the ones giving a positive reaction by means of a macro-Meinicke clarification reaction. By this means a correct diagnosis is likely to be arrived at in at least 99.7 per cent of the cases. The procedure for cerebrospinal fluid consists of testing all fluids by means of a macro-Meinicke clarification reaction, and checking the negatives by a Sachs-Witebsky. The likely errors would probably number only 2 per cent.

**Alleged Hemoclasia in Insane.**—Power and Pettit failed throughout their investigations to find any reasonable grounds for concluding that, among the insane, there occurs either a digestion leukocytosis or a digestion leukopenia. Variations in a succession of blood counts developed in a large number of patients, whether the latter had been given milk or were fasting, and there was no definite evidence that the taking of food had any effect whatever on the leukocytic curve. It is just possible that the hourly and daily rhythm of the leukocytes, described by Sabin and Shaw, may not be exactly the same in the mentally deranged as among normal individuals; but this must be a matter for future research and has nothing to do with the subject of hemoclasia.

**Error in Enumeration of Leukocytes.**—Yates and Batt show that certain errors are inevitable when leukocytes are enumerated, and demonstrate that results from such enumerations must be interpreted with mathematical considerations. In the past the mathematical applications have been ignored to a large extent, and only the actual experimental figures considered. The authors endeavor to correlate the two, and refer to fallacies that may be present when conclusions from such results are under consideration. Thirty-six cases investigated for hemoclastic crises gave results within the experimental error. A review of the literature on hemoclastic crises shows that many authors underestimate the error of counting.

*Pathology and Treatment of Anemia. L. J. Witts.—p. 653.
Treatment of Clonic Facial Spasm by Alcohol Injection and by Nerve Anastomosis. W. Harris and A. D. Wright.—p. 657.
*Occurrence of Pituitary Hormones in Urine in Conditions Unassociated with Pregnancy. T. N. A. Jeffcoate.—p. 662.
Operation Under Local Anesthesia: Preparation and Care of Patient. W. Moffatt.—p. 666.

**Pathology and Treatment of Anemia.**—Witts presents data on the basis of which he separates the hemolytic anemias from pernicious and allied anemias, and subdivides the hemolytic anemias into acute and chronic forms. Acute hemolytic anemia and the hemolytic anemia of pregnancy differ from pernicious and allied anemias in the absence of any nutritional or digestive defect, in the fever and general constitutional disturbance, in the regenerative character of the anemia with reticulocytosis and leukocytosis, in the fluctuations in the resistance of the red cells, and in the self-limited course. They differ from chronic hemolytic anemia in clinical features, natural history, and response to treatment. They may be so acute that hemoglobinuria develops, or they may be subacute and torpid; but death or spontaneous recovery occurs within a period rarely longer than a year. On the other hand, one must be impressed by the close resemblance of acute hemolytic anemia and the hemolytic anemia of pregnancy. Every feature of the one disease is duplicated in the other, and they differ only in the fact of pregnancy. For the peculiar frequency of a disease in youth and in pregnancy, one has a parallel in acute yellow atrophy of the liver. For the initiation or recrudescence of an anemia in pregnancy there is a parallel in the bartonella anemia of experimental animals, which may develop only under special conditions, such as after splenectomy or after artificial hemolysis, though the micro-organisms were previously present in the host. There is no valid reason in pathology for the separation of acute hemolytic anemia and the hemolytic anemia of pregnancy, and every symptom points to their identity.

**Pituitary Hormones in Urine Apart from Pregnancy.**—Jeffcoate gives experimental results confirming the work of other observers who have stated that prolan A can be found in the urine at the menopause after castration and in some cases of malignant disease. In a series of cases studied by the author, prolan B was never excreted in the urine except when the patient had living chorionic elements present in the body. In other words, a positive Aschheim-Zondek reaction never obtained except in the presence of such elements. It is shown that prolan A can be detected in the urine of rabbits after castration. Prolan A was found also in the urine of patients who had had subtotal thyroidectomy performed for exophthalmic goiter. The finding of prolan A in the urine of patients with malignant disease was almost entirely confined to those cases in which the genital tract was the site of the tumor.

Fable of Loaded Cecum. H. C. Trumble.—p. 301.

**Cardiac Arrhythmias.**—Murphy enumerates the causes of heart block as follows: (1) Acute infections, such as rheumatism, diphtheria and pneumonia; (2) chronic infections, such as syphilis; (3) degenerative changes—coronary sclerosis or fibrous myocarditis; (4) new growths or hydatid cysts—situated in the bundle of His, and (5) digitalis in large doses. The important features in heart block are the condition of the heart muscle generally; in acute infections, mild heart block may be the only sign of some myocardial damage. The occurrence of syncopal or epileptiform attacks may lead to difficulty. They are distinguished from true epilepsy, because there is no aura—the attack comes on quite suddenly without warning, and it is associated with a very slow pulse. The convulsion and loss of consciousness are due to the cerebral anemia produced during the period of complete block, before the ventricle takes on its own rhythm. It is not uncommonly fatal. Patients who suffer in this way should be warned against going out alone, and they should not expose themselves to any risk of falling down in the traffic. With the less severe forms of heart block, a fairly active life may be led for an indefinite period. A 1:1,000 solution of epinephrine in doses of from 0.3 to 0.6 cc. (5 to 10 minims) in the attack is frequently successful. Digitalis may be given in complete block and congestive failure. Atropine, 0.4 to 0.6 mg. ($\frac{1}{150}$ to $\frac{1}{100}$ grain), will act in those cases associated with vagal irritation. Barium chloride, 0.12 Gm. (2 grains), has been advocated. When some systemic disease such as syphilis is present, antisyphilitic treatment must be undertaken. Mercury in these cases appears to be safer than the arsenic preparations, and many patients are completely cured.

**Relation of Sluder's Neuralgia to Trigeminal Nerve.**—Cox describes section of the sensory root of the trigeminal nerve in a patient with a Sluder's neuralgia following an empyema of one sphenoidal sinus. The operation was done in three stages, but no effect was produced until the conjunctiva became hypesthetic. It is suggested that the condition is a neuralgia of the nasociliary nerve of infective origin. The author discusses atypical facial neuralgias and their relation to Sluder's neuralgia, and to the anatomy of the facial region.

**Case of Septicemia Cured by Injection of Bacteriophage.**—Brulé and Sauvé's patient consulted them because of furunculosis. A large abscess was cured by them with local bacteriophage treatment. He returned three months later in a serious condition; a diagnosis of septicemia was made, confirmed by a positive blood culture (Staphylococcus aureus). The symptoms of septicemia had set in eight days following a large injection of vaccine. Finding no general improvement after surgical intervention in the femoral osteomyelitis, the authors gave an injection of bacteriophage in a peptone-free medium, following a blood transfusion. This was followed two days later by an autohemotherapy of 20 cc., after which the temperature dropped, the blood cultures remained negative and a great improvement in the general condition of the patient, leading finally to cure, resulted. Reviewing the case, the authors point out the danger of transforming a latent infection into a generalized septicemia by the injection of a large quantity of vaccine and that the way to obtain a substantial production of antibodies is by progressive and methodical vaccination. Discussing the parts played by the bacteriophage and the autohemotherapy in effecting the cure, the authors suggest that the autohemotherapy destroyed the antiphages, thereby permitting the exclusive action of the bacteriophage.

Relations Between Pharmacologic Action and Optic Rotation of Substances. L. Rosenthaler.—p. 305.
*Magnesium Sulphate in Treatment of Tetanus. M. Saegesser.—p. 306.

**Pericancerous Inflammation.**—Neumann shows that pericancerous inflammation, which is well known in pathology, has been largely disregarded in the clinic and in practice. He recommends that it be given careful attention, for it is often possible to influence the carcinoma favorably, particularly in inoperable and ray refractory cases. The treatment of the pericancerous inflammation may be general and passive as well as active. In discussing the general treatment, the author emphasizes the necessity of careful handling in manual and in instrumental examinations, and advises that they should be avoided as much as possible. He also points to the dangers of exploratory excisions. For active therapy the author recommends medicinal antiinflammatory treatment, and for this purpose he considers guaiacol valerianate especially valuable, as it inhibits inflammations in general and also has antispasmodic effects. However, in case of hemorrhage of the mucous membrane of the gastro-intestinal tract, guaiacol valerianate is contraindicated. But, in the majority of cases, small doses are helpful. The author's main object was to show that in the cancer treatment of today one considers almost exclusively the tumor as such and neglects to consider and treat properly the pericancerous inflammation. He is convinced that the proper treatment of the latter could reduce the painfulness, especially in inoperable cases, and in some instances might even arrest the further growth.

**Magnesium Sulphate in Treatment of Tetanus.**—Saegesser points out that, as serotherapy has gained in significance in the treatment of tetanus, magnesium therapy has been largely disregarded. Accordingly he investigated whether serotherapy makes magnesium treatment superfluous. He made experiments on rats and found that after tetanus has become manifest it can be influenced neither by subcutaneous nor by intramuscular injection of magnesium sulphate, for the animals treated thus died at the same time as the control animals. The simultaneous injection of magnesium sulphate and tetanus toxin retards neither the outbreak of the tetanus nor the death of the animals. A preliminary injection of magnesium sulphate farther proximal from the site of the toxin injection retards the tetanus and makes the course more mild, so that the animals survive the tetanus. If instead of magnesium sulphate the same amount of physiologic solution of sodium chloride is injected into the tail, the course of the disease is the same in the animals that have received the injection as in the controls; that is, they die within the first ten hours. From these experiments the author concludes that in animals the perineural and intralumbar injection of magnesium sulphate blocks the central nervous system against the tetanus toxin. In the test tube it could be observed that toxin which has been absorbed by the cerebral substance can be liberated by the addition of magnesium sulphate. The author considers the perineural and intralumbar injection of magnesium sulphate in combination with the intravenous injection of large doses of serum a promising therapeutic method for human tetanus.

Clinical and Anatomopathologic Observations on Two Cases of Noma. A. Cavazzuti.—p. 105.

**Plastic Operation for Subumbilical Hernia After Laparotomy.**—Comolli illustrates and advocates his new method based on a single case in which it was impossible to keep the rectus muscles in place, because of separation and atrophy. The procedure consists in cutting the two gracilis muscles at their distal extremity, leaving the proximal insertion intact, passing them through a subcutaneous tunnel to the lower edge of the abdominal incision, and placing them one beside another over the umbilicopubic line in front of the previously sutured breach between the rectus muscles.

**Primary Sarcoma of Rectum.**—Montanari Reggiani states that the rectum is seldom the seat of primary tumors of connective tissue origin and that the clinical diagnosis of rectal sarcoma is still difficult. He briefly discusses the existing literature and describes the case history of a patient with fusocellular sarcoma of the rectum and sarcomatous metastases, first of the liver and then of the lungs by the circulatory route.

*Fibromyoma of Uterus: Spontaneous Evacuation. M. Nizza.—p. 51.
Rare Case of Survival of Very Premature Child. C. Cantone.—p. 60.

**Fibromyoma of Uterus: Spontaneous Evacuation.**—Nizza takes only large fibromyomas into consideration, the smaller ones being more frequent and inconsequential. He finds that they result often from lack of personal hygiene and that profuse menorrhagia is the first symptom. The expulsion of the tumor is conditioned by its growing protrusion inside the uterine cavity, which initiates the necessary mechanisms. The following factors determine expulsion: 1. The increasing growth of the tumor with repulsion of surrounding tissues. 2. The pressure exerted by surrounding fibromatous nodules. 3. Contraction of the uterus, as in the pains of parturition. Parturition favorably influences spontaneous expulsion. The uterine contractions mobilize the tumor, facilitating its passage through the genital tract, and even beyond any resistance offered by the pedicle. Laceration of the pedicle is the final consequence of the parturition. Uterine inversion indicates that the tumoral insertion is located at the lower part of the uterus and is favored by sessile fibromyomas or by short and excessively resistant pedicles with flaccidity of the uterine tissue. The adhesion of the fibromyomas to the wall of the vagina is due to prolonged contact and deprivation of the epithelium occasioned by circulatory disturbance and pressure.

Postoperative Course in Gynecologic Interventions. W. Fröhlich.—p. 738.

**Forms of Ovarian Tumor Known as Type Brenner.**—Meyer shows that Brenner's tumor is a macroscopically as well as microscopically well defined type of tumor of the ovary and that it is not related to the granulosa cell tumor, for it has neither a hormonal action on the uterus nor other noticeable functions. Brenner's tumor occurs sometimes in the solid form, but it may also contain cysts. Characteristic for Brenner's tumor are indifferent glycogen-containing cells with carcinoma-like arrangement in epithelial strands without interposition of fibrils in the epithelium. There is a tendency to swelling and to the formation of smaller or larger cavities with colloidal, mucous or mixed contents. Epithelial formations are found arranged in smaller or larger nests in a firm, fibrous connective tissue, which constitutes a large or by far the largest portion of the solid tumor. The epithelial portions of the tumor originate neither in the ovarian parenchyma nor in its preliminary stages (granulosa balls) but in special cells that have no relation to the normal tissue structure of the ovary, but rather are abnormal embeddings. Their development is traced to embryologic conditions. According to their genesis, the author considers Brenner's tumors as belonging to a systematic order together with the majority of the serous cystomas, adenomatous, papillomatous and partially fibromatous cystomas up to the adenofibromas and the mixed serous-mucinous tumors. Brenner's tumor is benign. Relapses and metastases are absent and it is found mostly in the higher age groups.

**Rare Causes of Severe Obstetric Hemorrhages.**—Naujoks first discusses premature, total detachment of the placenta. He considers the hematomas of the uterine wall as an early developing sequela of a toxicosis, the later and more serious complication of which is the detachment of the placenta. The diagnosis can be based not only on the known symptoms but also on the intra-amniotic hemorrhage, which becomes manifest following rupture of the bag of waters. In regard to the treatment, it is stated that in severe cases a laparotomy is necessary but extirpation of the uterus should be resorted to only in extreme cases. The author further discusses placenta praevia cervicalis. Its diagnosis can be based on hemorrhages that develop during the early periods of pregnancy and continue for some time. The dangerous aspect of this condition is not the cervical location of the placenta but rather the usually resulting placental adhesions with subsequent atony. Tamponade is not reliable as a treatment in placenta cervicalis, even after the entire placenta has been detached. The author advises particularly against tight tamponade of the cervix. Prompt and radical intervention is here more necessary than in any other obstetric complication. In regard to spontaneous inversion of the puerperal uterus, it is stated that the danger of shock should not be stressed too much and the danger of fatal hemorrhage should not be underestimated. If collapse does not exist, prompt reposition is advisable. An expectant attitude involves the danger of a fatal hemorrhage, and for this reason it is justified only in existing collapse. In the last part of the article the author discusses varicosis and formation of hematomas. He thinks that varicosis genitalis is given too little consideration. It may cause a number of serious complications during and after labor, of which the formation of hematoma is one of the most important. For the deep hematomas the author recommends conservative measures, and the smaller hematomas should if possible not be incised. In the case of larger hematomas, an early incision should be done only if absolutely necessary. A later incision, after several weeks, cannot usually be avoided, since the spontaneous resorption of the blood clots is unfavorable.

Types of Gastric Secretion. J. Fleckel.—p. 227.

**Peristalsis Stimulating Substance in Gastric Mucous Membrane.**—Onodera and his associates found that, by introducing from 40 to 60 cc. of a 20 to 25 per cent solution of magnesium sulphate directly into the duodenum, diarrhea is rarely produced. However, if the same quantity of magnesium sulphate is given by mouth, diarrhea usually results. This observation gave the authors the idea that by contact of the magnesium sulphate solution with the mucous membrane of the mouth, esophagus or stomach a substance develops which stimulates the peristalsis of the digestive canal. Accordingly, with the aid of a concentrated magnesium sulphate solution they made extracts from various portions of the oral, the esophageal, the gastric and the intestinal mucous membranes and also from several organs, and injected these extracts intravenously into animals and then studied the action on the tonus and the contractions of the intestinal wall. It was found that the gastric mucous membrane contains a substance that increases the peristalsis and minute amounts of this substance are also present in the spleen; however, all the other portions of the mucous membrane as well as the other organs that were tested did not contain this substance. The substance is readily dialyzable, boiling for a period of thirty minutes does not destroy it, and it differs somewhat from Zülzer's peristalsis hormone. One of the authors isolated from the magnesium sulphate extract of the gastric mucous membrane a crystalline substance, the aqueous solution of which, when injected intravenously, increases the tonus and the peristalsis of the stomach and of the intestine. The authors also made experiments with amino-acids and a 25 per cent solution of magnesium sulphate and obtained peculiar crystals of double salts, which differ from the crystals of the magnesium sulphate as well as from those of the amino-acids. The intravenous injection of the aqueous solution of these peculiar crystals had a peristaltic effect; especially strong was this effect with the double salts from magnesium sulphate and the aliphatic amino-acids, whereas the double salts of magnesium sulphate with the aromatic amino-acids had only a slight or an entirely negative peristaltic action. The authors conclude that the former assumption that the purgative action of magnesium sulphate is entirely due to its nonresorbability is not quite correct but that a small portion is absorbed, which with the aliphatic amino-acids forms a hormone-like substance with a peristaltic action. The largest portion of the magnesium sulphate, however, is not resorbed but keeps the intestinal contents in a fluid state. Thus the resulting diarrhea is due to two factors; namely, the increased peristalsis and the fluid condition of the intestinal contents.

**Tuberculosis of Bone System.**—In generalized hematogenic miliary tuberculosis, Randerath demonstrated in all carefully examined cases the presence of miliary tubercles in the bone marrow. In this form of tuberculosis the nodules were found mainly in the myeloid portions of the bone system, whereas the pure fat marrow portions contained but few tubercles. In some cases of miliary tuberculosis, tubercles were entirely absent from the fat marrow. This contrast in the density of the tubercles in the myeloid marrow and in the fat marrow was noted in all cases. In examining the bone marrow in chronic, isolated pulmonary tuberculosis the author noted an unusual frequency of miliary tubercles in the bone system. In eighteen out of twenty-two cases, miliary bone marrow tubercles were found. In contradistinction to general miliary tuberculosis, the nodules in this group showed certain peculiarities in regard to their developmental stages. In one group, all tubercles in the bone marrow showed the aspects of "primary tissue impairment," in the sense of more or less advanced circumscribed necroses. In another group, all the tubercles in the bones belonged to the productive stage. And in a third group there were in the bone marrow, similar to conditions found in generalized miliary tuberculosis, all developmental stages of tubercles side by side. In examining cases of chronic isolated tuberculosis of the bone system, the author found sometimes more caseous and then again more granulating productive processes. But a strict differentiation of bone tuberculosis in a caseous and a granulating form, he does not consider justified, since the two stages merge into each other.

**Carbon Treatment of Pulmonary Tuberculosis.**—Sommerlad shows that of the various forms of nonspecific stimulation therapy for pulmonary tuberculosis the carbon treatment deserves special consideration, not only because it can be employed in a larger number of cases but also because it is less dangerous than is treatment with metal salts. The carbon treatment has the aim to increase the natural defensive action of the reticulo-endothelial system. The suspension that the author employed for intravenous injection is ready prepared in ampules of from 3 to 4 cc. It consists of small carbon particles in an isotonic calcium chloride solution. The injection is made slowly, and care is taken that the carbon particles are evenly distributed in the suspension. From five to ten hours after the injection there is usually an increase in temperature and also headache, weakness, pains in the joints, lack of appetite and in rare instances also chills and nausea. The temperature increase usually recurs on the following day, but on the third day it has usually reached the former level. With the reduction in temperature the other symptoms likewise disappear, and on the fourth or fifth day the patients usually feel quite well again. For at least three days following the injection, strict rest in bed is required. The author reports his experiences with intravenous carbon injections in fifty-eight patients, most of them with severe pulmonary tuberculosis. In thirty-seven of them a considerable improvement was effected. The number of injections varied in different patients; some received three or four injections, while others received as high as eighteen. The indications for the treatment and the dosage are discussed and it is emphasized that the treatment should be given only in institutions and that it usually requires several months. The influence of the injections on the reticulo-endothelial system was carefully controlled by means of the blood pictures. Numerous roentgenograms are shown.

**Radium Treatment of Malignant Tumors of Oral Cavity.**—Berven emphasizes the better results that have been obtained in recent years with radium treatment of tumors of the oral cavity. He ascribes the more favorable results to the improved technic of recent years. His report covers the years from 1916 to 1926. In the first half of this period, from 1916 to 1921, the treatment was usually begun with roentgen irradiation and was followed by surface contact application of radium tubes. After 1921 the brachyradium therapy in the form of surface contact application or of intratumoral application was gradually discontinued and teleradium treatment (from 5 to 6 cm. distance) was employed. The teleradium treatment was given in such a manner that the cone of rays attacked the tumor from various sides. The author gives tabular reports which show the number of cases of lingual, sublingual, mandibular and buccal carcinomas that were treated during the years from 1916 to 1921, and during the period from 1921 to 1926, and the percentage of cures in each group. In another table the carcinomas are grouped according to stages during which treatment was begun and the result obtained in each stage, and other tables show the results obtained in lympho-epithelioma of the tonsils and in sarcoma of the tonsils. In the conclusion the author points out that because the teleradium therapy requires great experience it should be given only in special clinics.

**Epituberculous Infiltration of Lung During Childhood.**—Blacher in his comprehensive study first discusses the various terms that have been applied to the epituberculous infiltration and also the different opinions about its pathogenesis and its significance. His own observations were made on 214 cases of acute tuberculous disease. He found epituberculous infiltration in only 5 per cent of these cases and therefore concludes that it is comparatively rare. He gives ten detailed case reports and on the basis of his observations concludes that epituberculous infiltration is a manifestation of a defense reaction on the part of the pulmonary tissue surrounding the primary focus. The case histories indicate that the age of a child and perhaps also the localization of the tuberculous infiltration are significant for the course of the process. In all younger children, regardless of the localization, and in all infiltrations of the upper lobe, regardless of the age of the child, the healing tendency was retarded. The size and density of the infiltration do not permit an inference as to the size of the tuberculous focus and the type of the tissue reaction. The ready reactivity to tuberculin and other irritants indicates a tuberculous origin of the infiltrate. The pulmonary infiltration was often accompanied by a disease of the pleura. The latter sometimes preceded the infiltration and from this it may be assumed not merely that it is an accompanying manifestation but that it may be a factor in the pathogenesis of the infiltration. Three cases that were kept under careful roentgen control indicate the great significance of the primary focus for the development of the epituberculous infiltration. Of decisive significance for the pathogenesis of the epituberculous infiltration is the connection of two biologic factors, namely, the constitutionally conditioned reactivity of the entire organism referred to as "allergic diathesis" and the sensitization of the pulmonary tissue by the tuberculous infection.

**Treatment of Tuberculous Meningitis with High Voltage Roentgen Irradiation.**—Von Bókay thinks that the cause of death in tuberculous meningitis is not so much the tuberculosis as such but that the patient dies after the process has extended over certain areas; that death is the result of the injury of certain centers by inflammation and pressure. Accordingly he decided to counteract not so much the general tuberculous infection but rather the local foci. Because in pulmonary tuberculosis and in tuberculosis of the bones he had obtained favorable results with high voltage roentgen irradiation, he decided to try it also in tuberculous meningitis. A trial seemed the more justified since in tuberculous meningitis the mortality rate is almost 100 per cent. The treatment consists of a thorough irradiation of the brain and of the medulla oblongata. This requires a high tensioned and strongly filtered radiation. In order to increase the deep dosage, the focus distance was taken as wide as possible. The quality of the rays was individually determined according to the patient's condition. The treatment was usually given on three successive days and when necessary also on the fourth and fifth days. The rays were applied successively on adjoining fields. The author gives detailed reports of five cases in which this treatment effected cure, but in twelve other cases it was ineffective. That five patients could be cured justifies a certain hopefulness, particularly in view of the fact that formerly the prognosis was almost entirely unfavorable. The author hopes that his procedure may be tried on a larger material. He admits that the high voltage roentgen irradiation also involves certain dangers, such as partial or total loss of hair, which, however, is usually reversible; but even if the alopecia should prove permanent, it would be a slight disadvantage compared to the life saving possibilities of the irradiation.

**Thyroxine-Prolan Treatment of Obesity in Women with Early Amenorrhea.**—According to Schittenhelm and Eisler, prolan influences not only the ovaries but also the metabolism. They decided to employ it together with thyroxine for the reduction of obesity in women who also had menstrual disturbances, such as amenorrhea. The treatment was begun by giving for four days, three times daily, 3 mg. of thyroxine by mouth. Then the thyroxine was omitted and prolan was given instead, likewise by mouth (from 80 to 300 units). On the basis of their observations the authors conclude that a rightly conducted thyroxine-prolan therapy is effective in that it not only reduces the obesity but also aids the return of the menstrual flow. However, in women with normal menstruation, they consider the use of prolan dangerous and therefore advise against its prolonged administration in such cases.

**Experimental Contributions to Organ Anaphylaxis.**—A review of the literature convinced Róth and Szauter that the type as well as the intensity of the anaphylactic shock differs according to the site of reinjection. That the typical anaphylactic shock is characterized by pulmonary symptoms is due to the fact that in the usual modes of injection the antigen comes first in contact with the capillary sphere of the lung. If, however, the site of reinjection is chosen so that the capillary sphere, which first comes in contact with the antigen, is not the lung, the symptoms are essentially different. The authors describe tests on guinea-pigs and on rabbits. In a first group of animals they produced anaphylaxis of cerebral character by intracarotid reinjection. The symptoms were loss of consciousness, tonoclonic spasms and typical cerebral symptoms. In a second group of animals, intrajugular reinjection was done and the pulmonary symptoms predominated. In a third group of animals, in which intraportal reinjection was done, there were changes in the secretion of the bile and in the function of the liver. These functional changes in the organs correspond to the anatomic changes that were found. In the cerebral anaphylaxis there were intensive hyperemia of the brain, and in some instances capillary hemorrhages. The hyperemia was usually most marked on the side on which the injection was made. After jugular reinjection, the anatomic changes were found mostly in the lung: emphysema with edema, pleural hemorrhages, and in one case even subpleural transudate. In intraportal reinjection the surface of the liver showed the lobular outlines plainly, because of the dilatation of the interlobular vessels.

**Nasal Pruritus in Cerebral Tumors.**—Wartenberg points out that it is frequently noted that patients with cerebral tumors rub the tips of their noses and their nostrils, because of an intense itching. He describes two cases of cerebral tumors, in both of which this symptom was noted. The beginning of the nasal pruritus concurs with the signs of increased cerebral pressure. The pathogenesis of this sign is as yet not definitely known, but the author assumes that it is the result of irritation of the trigeminus. A review of the literature proved that this symptom had been noticed by others, but the fact that in a recent monograph on brain tumors it is not mentioned, and also his two recent observations, induced him to call attention to it again.

**Basal Metabolism During Pregnancy in Patients with Goiter.**—In an Alpine region where goiter is endemic, Niederwieser found that in pregnant women the basal metabolism is increased even if they do not have goiter. The average increase is about 15 per cent. The size of the goiter and its consistency have no noticeable influence on the basal metabolism, and the same can be said about the age of the gravida and the number of her confinements. However, there is a parallelism between the depth of respiration, which gradually increases with the advancing pregnancy, and the basal metabolism. The specific dynamic action is reduced during pregnancy, and the author thinks that this is due to the morphologic changes in the hypophysis. The goiter exerts no noticeable influence on the course of pregnancy. The thyroidal function of the new-born is influenced neither by the type and size of the mother's goiter nor by her basal metabolism.

**Skin Reaction for Demonstration of Deep Gonorrheal Processes.**—According to Neuer, the recognition of acute deep gonorrheal processes is usually possible on the basis of the anamnesis and of the examination of smears. However, chronic deep processes are less readily recognized. The Müller-Oppenheim complement fixation method is helpful, but it often involves difficulties and for this reason the author devised a simpler method; namely, a skin test by means of an ointment, containing killed gonococci. After the skin of the upper arm has been cleaned with ether, it is scarified on three places. To one of the scarified areas only an indifferent substance is applied, and to the two others the ointment is applied. If the test is positive the reaction is most severe after twenty-four hours; there is inflammatory reddishness and formation of small pustules on the site of vaccination. After a day these manifestations begin to disappear. In negative cases, neither the sites of vaccination nor the control scarification show a reaction. It is advisable to have always at least two areas of scarification, the one for vaccination and the other one for control. The results that the author obtained with this test tallied with the complement fixation reaction.

**Treatment of Primary Sciatica by Stretching of Sciatic Nerve.**—Toprower points out that surgical stretching of the sciatic nerve was first recommended by Billroth. Later it was employed indiscriminately by some surgeons and thus it came into discredit and was almost entirely abandoned. The author takes the stand that in suitable cases it is of great therapeutic value. He thinks that in the beginning stage sciatica should receive conservative treatment. However, if within six months this treatment does not effect improvement, surgical stretching should be resorted to. From observations in twelve cases in which this treatment was employed, the author concludes that in cases of chronic primary sciatica surgical stretching of the nerve is effective. However, in typical neuritis of the sciatic nerve, with muscular atrophy and sensitiveness to pressure along the entire course of the nerve, and in diseases of the central nervous system, surgical stretching is not advisable.

**"Tetanigenic Substance" in Urine of Spasmophilic Children.**—Hertz repeated Nitschke's experiments by which the latter had demonstrated in the urine of spasmophilic children a substance that proved tetanigenic for rabbits. However, he was able to demonstrate the tetany toxin in only five out of eleven cases of spasmophilia. He thinks it probable that the diet of spasmophilic nurslings influences the outcome of the animal experiment but has as yet not proved it. With the urinary sediment of nonspasmophilic children, who had other disorders, it was possible to produce in six cases a reduction of the calcium content of rabbits. The age of the children is evidently of no importance in this connection. The substance that is tetanigenic for rabbits, therefore, does not necessarily have to produce spasmophilic symptoms in patients who eliminate it with their urine. Thus there is as yet no definite proof for a relation between tetany in infants and the artificial spasmophilic syndrome in rabbits. The solution of this problem depends on a better isolation of the tetany toxin postulated by Nitschke. So far it can only be said that in the urine of children with considerable disintegration of cells or with marked disturbance of the metabolism (among others also spasmophilia) a mixture of substances is eliminated which reduces the calcium content of the serum of rabbits and thus produces in these animals symptoms that indicate irritation of the nervous system.

**Influence of Vegetables on Nitrogen and Mineral Metabolisms of Children.**—Edelstein found that by adding spinach or carrots to the milk diet there is almost regularly a reduction in the retention of nitrogen, of ash, of calcium oxide and of phosphorus pentoxide. It is probable that the reduction in the retention is due to a lessened utilization in the intestine. In the influence on the retention there is no difference between fresh vegetables and canned vegetables. However, besides their influence on the utilization, the vegetables have yet other functions in the organism: they act as regulators by providing roughage and also are sources of vitamins.

**Actions of Viosterol.**—Strauss cites reports from the literature in which large doses of viosterol resulted in severe cachexia and death of the animals, and the necropsies revealed calcium deposits and degenerative processes in the vital organs. On the other hand, some experimenters noted a loss of calcium in the skeleton of animals fed with large doses of viosterol. In general, the injurious effects were noted only after excessive doses; however, they have also been noted after comparatively small doses. The author reports the case of a rachitic child, aged 18 months, to whom 100 mg. of viosterol had been administered in the course of two and one-half months. He describes the observations during the necropsy, particularly the calcification processes in the skeletal system. He noted that, as in the spontaneous cure of rickets, a new zone of calcification develops far toward the epiphysis, whereas the proliferated cartilage of the rachitic zone remains uncalcified. The osteoid trabeculae of the diaphysis and of the metaphysis calcify likewise to a considerable extent, but certain sections remain free from calcium. Later in the healing process new osteoid margins develop, which in regard to surface as well as depth far exceed the normal; that is, they still have some rachitic characteristics. The author discusses three possible explanations of the calcification process in the rachitic bone: (1) the humoral theory, (2) that perhaps the viosterol exerts a certain influence on the colloids by producing an increased calcium affinity, and (3) that the influence on the bone cell itself is the primary action of the viosterol.

**Carcinoma-Inducing Principle in Oils and Tars.**—Twort and Fulton show that carcinoma-inducing substances can be prepared synthetically from many organic substances. For the concentration of the carcinoma-inducing units in synthetic tars distillation is helpful, and to a certain extent distillation is also helpful for the concentration of the carcinoma-inducing units in mineral oils. Saturation by oxidation or reduction of agents of the nature of hydrocarbons apparently always reduces the carcinoma-inducing units. The action of organic enzymes is doubtful; it appears that living yeast cells reduce the number of carcinoma-inducing units, probably because they act as reductases. Filtration of an oil through silicic acid gel or through clay reduces the carcinoma-inducing units in the filtered as well as in the remaining substance, and it is probable that adsorption and polymerization are the most important factors. The action of ultraviolet rays and of radon reduces the carcinoma-inducing units. Methyl sulphide, trinitrophenol and alcohol primarily extract the carcinoma-inducing substances and their accompanying defense substances. Treatment of mineral oils with sulphuric acid reduces their carcinoma-inducing units. Mercury acetate in acid solution reduces the number of carcinoma-inducing units, whereas the neutral solution exerts only a slight influence. Attempts were made to determine the amount of carcinoma-inducing units in liquid petrolatum by physical and by chemical means. Among the various procedures that were tried, the specific gravity, the refractive index and the iodine number were found to be the best indicators, but there may yet be other methods that may prove helpful. The authors think that it may eventually be possible to dispense with the use of animals for testing the carcinoma-inducing action of oils.

New Self-Holding Vaginal Speculum. H. Högler.—p. 747.

**Term of Conception in Women.**—From careful studies, Ogino concludes that the term of conception as a rule lasts eight days. It extends from the nineteenth to the twelfth day before the succeeding menstruation. In the time between the twenty-fourth and twentieth day before the next menstruation, a conception is extremely rare, but there are as yet not sufficient observations to exclude the possibility of a conception during these four days; because of the rarity of conception during this period, however, it can be considered as practically sterile. But during the eleven days before the onset of the next menstruation conception is impossible. The author thinks that the determination of these factors will enable women who have to practice sexual abstinence or resort to contraceptives to do without these at least during some periods. For practical purposes it is advisable to determine the period of conception from the onset of the last menstruation. If the cycle lasts twenty-eight days the time of conception is between the tenth and seventeenth day after the onset of the last menstruation. If the cycle is longer or shorter than twenty-eight days, the term of conception is shifted by so many days backward or forward. Since there are comparatively few women in whom the menstrual cycle is always of the same duration, the formula for the time of conception has to be expressed as follows: Beginning of term of conception is ten plus (minimal duration of cycle minus twenty-eight days). End of term of conception is seventeen plus (maximal cycle minus twenty-eight days). The maximal and minimal duration of the cycle have to be determined from the last twelve series of cycles; to take into account only three or four cycles is not sufficient. However, since most women do not keep a record of their menstrual cycles, they have to give the maximal and minimal duration from memory. The formula mentioned is of value only for women in whom the menstrual cycle has a maximal fluctuation of not more than ten days. The greater the fluctuations, the lesser the value of the formula.

**Ligation of Uterine Vessels in Hemorrhages in Placenta Praevia.**—In anatomic hemorrhages or in hemorrhages caused by tears following vaginal delivery in placenta praevia, Kerwin recommends bilateral ligation of the uterine vessels through the vaginal wall. The method does not require special instruments but only those that every obstetrician has at his disposal. By means of a large round needle a strong catgut thread is introduced into the parametrium, where the vaginal wall meets the cervix. The point of the needle is directed upward toward the uterus and comes out again through the vaginal wall 3 cm. lower. The suture is tied, and the same procedure is repeated on the other side. The vaginal wall remains unimpaired except for the opening at which the needle entered. The hemorrhage ceases immediately after the second ligation is completed. Nine women, who were threatened by death from severe hemorrhage, were saved by this method. Two of them have since had spontaneous deliveries. The method is suitable for the clinic as well as for obstetrics in the home.

Carcinoma in Young Adults. K. Kosieradzki —p. 193
Tumors: Polish Bibliography for Second Semester of 1930. A. Czyżewicz. —p. 223.

**Internal Secretions and Experimental Malignant Tumors.**—Karnicki investigated eight series of experimental rabbits, besides the control series, in order to find the relation between the internal secretions and experimental carcinoma. Gas tar was used as an irritant. The rabbits in the eight series were subjected to (1) thymusectomy, (2) thyroidectomy with unilateral parathyroidectomy, (3) testectomy, (4) unilateral suprarenalectomy, (5) thymusectomy combined with testectomy, (6) implantation of thymus and testes, (7) experimental carcinoma plus injections with extracts from the previously excised glands, and (8) hypophysectomy. The animals of the eighth series did not survive the operation. The results reported by the author were as follows: 1. The glands of internal secretion have an influence on the genesis and development of experimental carcinomas in rabbits. 2. Thymusectomy accelerates the appearance of experimental tumors in the relation of 4 to 1. 3. Thyroidectomy with unilateral parathyroidectomy hastens also the formation of tumors in the relation of 3 to 1. 4. Testectomy produces less acceleration than thyroidectomy with unilateral parathyroidectomy and considerably less than thymusectomy. 5. After unilateral suprarenalectomy there is a marked retardation of both the appearance and the growth of tumors. 6. The acceleration of the appearance of tumors after thymusectomy combined with testectomy in the same animal is marked. 7. Implantation of thymus and testes considerably retards the appearance of tumors. 8. Injections of extracts from thymus and testes cause dehydration and breakdown of tumors, also shrinkage of the larger nodules and destruction of the smaller ones. The large nodules soften in the later phases of the injection periods. From this time on, even increased doses do not cause further reduction of the nodules. After the injections have been suspended, also, further growth does not follow.

Medical Reports on Social Medicine. J. Szumski.—p. 202.

**Basophilic Bodies in Gaucher's Disease and Value of Sternal Puncture.**—In the case of Gaucher's disease described by Sokolowski, the material obtained by splenic puncture was stained by several methods. The most distinct preparations came out when the May-Grünwald-Giemsa method was used. In these preparations there were, besides the known cells, minute, roundish, granular bodies, basophilic, scattered more or less in groups, and occasionally surrounding the roundish nuclei. In the specimen from the sternal bone marrow were found certain cells, corresponding completely in every detail with the cells described in preparations from the splenic pulp and known as Gaucher's cells. The author concludes that: 1. For diagnostic purposes in suspected Gaucher's disease it may not be necessary to perform splenic puncture as long as the sternal (manubrium) bone marrow contains the material, with abundance of characteristic cells. 2. The basophilic bodies described represent a detail which contributes to the symptomatology of Gaucher's disease.

**75:** 299-326 (Feb. 11) 1932

*Course of Complement Fixation Reaction in Gonorrhea in Men. V. Genner, K. Antons, and H. Boas.—p. 299.
*Blood Sedimentation and Basal Metabolism. G. Bredemose.—p. 319.
Case of Fatal Genital Gangrene. G. Bindslev.—p. 322.

**Course of Complement Fixation Reaction in Gonorrhea in Men.**—Genner and his associates made complement fixation tests in sixty-six patients with gonorrhea during the disease and in most cases after clinical recovery. They say that in epididymitis and in arthritis with acute onset the reaction rises rapidly according to the clinical acuity, often reaching the maximum in the course of a week, and falls slowly, usually becoming negative in from six months to two years, somewhat sooner in epididymitis than in arthritis. In prostatitis the rise is less rapid and the reaction apparently remains positive somewhat longer than in epididymitis. The reaction is a valuable supplement in cases with doubtful exploratory results and seems to show that many cases regarded as posterior urethritis are really instances of latent prostatitis. A positive reaction occurred in a small number of control cases; such cases the authors would for the present designate, not as "nonspecific," but as "cases with positive gonorrhea reaction as the only symptom."

**Blood Sedimentation and Basal Metabolism.**—Bredemose finds that the sedimentation reaction recommended by Goldmann and Taterka as preferable to basal metabolism tests for determining the therapeutic effect in cases of hyperthyreosis and hypothyreosis is without practical value for this purpose.

**75:** 327-370 (Feb. 18) 1932

*Malignant Trigeminal Neuralgia: Treatment with Radical Operation. F. Djørup.—p. 327.

**Malignant Trigeminal Neuralgia.**—In the sixty-eight severe cases reported in detail by Djørup, the condition, mostly of many years' standing, was so resistant to all other operative measures and to the various medicinal treatments that resection of the gasserian ganglion or retrogasserian neurotomy became necessary as a last resort. Forty-one patients (thirty operated on during the last five years, eleven more than five years ago) are without pain, although in twenty of these primary or secondary complications cause a certain inconvenience; seven are improved, ten unchanged and ten dead. He considers it more and more evident, in spite of the occurrence of complications and the technical difficulty of the operation, that retrogasserian neurotomy is about to become the safest and best means of operative treatment in malignant trigeminal neuralgia in its gravest forms.

**75:** 371-398 (Feb. 25) 1932

*Postoperative Phlebitis, Thrombosis and Embolism. E. Dahl-Iversen and E. Ramberg.—p. 371.

**Postoperative Phlebitis, Thrombosis and Embolism.**—A study made by Dahl-Iversen and Ramberg of 18,168 operative cases with 636 cases of postoperative phlebitis, thrombosis and embolism shows no increase in these complications during the last twenty years. According to the present status of knowledge, they assume that the origin of thrombosis after aseptic operative treatment depends on the interplay of three factors: (1) changes in the blood plasma and in the relation of the formed elements, (2) retarding of the blood stream, and (3) probable changes in the endothelial cells of the blood vessels. For prophylaxis they advise reduction of the cell degeneration accompanying every operation by careful hemostasis, avoidance of contusion of the tissue in the operative field, and inclusion of as little tissue as possible in the ligatures; in preoperative treatment, reduction of the loss of fluids in the organism, avoidance of unnecessary inanition, administration of large quantities of fluids, and exercises in deep respiration and in movement of the patient in bed; in postoperative treatment, application of the same principles as in preparatory treatment. Compression bandages on the lower extremities and elevation of the foot of the bed are also recommended.

# CARCINOMA OF THE CERVIX UTERI

## A STATISTICAL SURVEY OF TWENTY-ONE YEARS OF TREATMENT

EUGENE S. AUER, M.D.

ST. LOUIS

This study is based on an analysis of the result of treatment of all cases of cancer of the cervix seen at the Barnard Free Skin and Cancer Hospital from 1906 through 1926, the first twenty-one years of its existence. During this time the gynecologic service was in charge of Drs. George Gellhorn and F. J. Taussig, who alternated every six months. The service, up to recent years, has consisted largely of far-advanced cases, owing to the fact that other hospitals have sent many patients to our free cancer wards. Comparisons of statistics from different institutions are of little value. More information is obtained by setting side by side the results of different methods of treatment at various times in the same place and under similar conditions. For this reason, an analysis of our material promises to be instructive.

This study is based on 634 patients suffering from carcinoma of the cervix, of whom 498 were treated while the remaining 136 received no treatment except medicine and general advice. The cases have been divided into two major groups: those treated from 1906 to 1916 inclusive and those treated from 1917 to 1926 inclusive. The reason for this division is the fact that radium was obtained in 1917 and brought about a radical change in the cancer therapy at our hospital.

A study of the figures, as will be seen later, discloses a lower five-year cure rate than is usually reported. A large factor is the geographic location of this clinic and the source of our material. A large fraction of our patients come from Arkansas, Missouri, Mississippi, southern Illinois, Kentucky and Tennessee. During the years of the study, the vital statistics in some of these states were incomplete so that we were not always able to follow up our patients after they had been discharged; and on general principle we count every patient whom we cannot locate as dead from cancer. In this respect we are less fortunate than workers in Eastern centers, where follow up is easier. A considerable number of patients from this area were unable to communicate with the clinic, owing to illiteracy.

As has previously been stated, 634 cases of primary cervical cancer were seen in the twenty-one years covered by this report, of which 498 were treated in the outpatient department and hospital. The total percentage of cure (table 1) is relative, as it is based only on the number of cases treated rather than those seen. One hundred and thirty-six patients did not receive any treatment either because they absented themselves or were in an altogether hopeless condition; others were referred back to their family physician or were not entitled to free service. After the introduction of radium in 1917, however, even the apparently hopeless cases were given the benefit of radiation.

Table 1 shows that cures of five years were obtained in but 9.64 per cent. This low percentage is in part explained in table 2, which shows the large number of patients (17.6 per cent) who could not be located. It must be repeated that all patients not accounted for were listed as having died of cancer.

Table 3 shows the age incidence of the patients coming to the clinic. During the early years of the study our records were relatively incomplete, thereby causing some discrepancy in the figures. It will be noted that almost a majority of the cases fall into the age group of 40 to 55, commonly known as the "cancer age." However, attention is called to the fact that 29.09 per cent of the patients seen were under the age of 40.

Table 4 demonstrates the cases treated year by year and the results obtained by the various methods of treatment. In addition, some idea of the permanence of the cures is obtained from the large number (thirty-five) alive at the end of 1931. Of the remaining thirteen patients, now dead but who remained free from cancer five years after treatment, only six died as a result of carcinoma.

We have classified the cases of both major categories into clinical groups according to the extent of the disease (table 5). This classification was determined solely by the physical examination. Group 1 comprises those cases in which involvement was limited to one half or less of the cervix. Group 2 comprises those cases in which more than half of the cervix was involved but in which there was no palpable vaginal or parametrial extension, although one or the other could occasionally be demonstrated microscopically. Group 3 comprises those cases in which the malignant process had invaded the vaginal wall without perforation and/or parametrial thickening to one pelvic wall. The other parametrium might be involved but was not infiltrated to the pelvic wall. Group 4 includes all cases in which there was total fixation of the uterus, due to parametrial infiltration, fistula or metastasis to distant organs, bones or glands.

An analysis of five-year cures for the first group of cases, 1906 to 1916 inclusive, during which time no radium was available for treatment, is seen in table 6. The methods of treatment during this period were excochleation, acetone locally, pancreatic treatment, copper treatment, and radical surgery. It is almost superfluous to state that the only cures established were

---

From the Gynecologic Service, Barnard Free Skin and Cancer Hospital.

by means of surgery. The proportion of cures (27.2 per cent in group 1 and 26.66 per cent in group 2) does not compare unfavorably with other figures reported for that period. The operability rate during this period was 17 per cent, although "inoperable" cases were occasionally subjected to operation but without success.

| Total cures: 1906 to 1926 | | 48, or | 9.64% |
| 1906 to 1916 | | 7, or | 4.76% |
| 1917 to 1926 | | 41, or | 11.68% |

TABLE 2.—*Patients Lost Before the End of the Five Year Period* *

| Period | Number of Patients |
|---|---|
| 1906 to 1916 | 46 |
| 1917 to 1926 | 42 |

* Some of these patients were lost as late as four years and six months after treatment, but all go into the statistics as having died of cancer when lost.

TABLE 3.—*Ages of Patients*

| Age | Number of Patients | Per Cent |
|---|---|---|
| 22 to 30 | 18 | 3.68 |
| 30 to 35 | 45 | 9.22 |
| 35 to 40 | 79 | 16.19 |
| 40 to 55 | 225 | 45.81 |
| 55 to 60 | 63 | 12.91 |
| 60 to 70 | 45 | 9.22 |
| 70 to 90 | 13 | 2.66 |

A similar analysis for the second group of cases, from 1917 to 1926 inclusive, is seen in table 7. In this series the operability rate was 15.6 per cent, compared with 17 per cent for the earlier series. This lowering of the operability rate was due, no doubt, to the sudden influx of far-advanced cases that were received during the latter portion of 1917 and during the entire year of 1918. The knowledge that radium had become available in the treatment of carcinoma in this clinic was responsible for many obviously incurable patients presenting themselves to us at this time. Referring back to table 4, it will be seen that in 1918 thirty new cases were treated with but one five-year cure. Such a figure is not duplicated anywhere in this series, the next lowest year being 1919, when the percentage of cure was 10 per cent, exactly three times that of 1918. In table 7, the proportion of five-year cures of group 1 is 54.17 per cent, treated by all methods, a figure that may well be called satisfactory. The results in the other three groups are also fairly satisfactory. Our poor salvage rate of but 3.20 per cent in group 4 cases can be explained by the extremely far-advanced condition that was found when these patients presented themselves to us.

A comparison of all cases treated by operation or with radium during the years 1917 to 1926 is seen in table 8. The surgical cures were accomplished solely by means of radical operations of the Wertheim or Schauta types with the exception of one patient, who remained well after a radical ignicauterization by the Byrne method. In groups 1 and 2 there can be noted a definite advantage of the results of surgery over radiation. In the remaining cases, radiation offered the only hope of a cure. Of thirty-one cases of all groups subjected to operation, 48.38 per cent remained well and free of cancer for at least five years. Three hundred and twelve patients were treated with radium; of these, only 8.33 per cent survived the five-year period, but of course there were among them a majority in the advanced stage of the disease.

TABLE 4.—*Cures by Years*

| Year | Number of Cases Treated | Cures | Per Cent Cured | Living, January, 1932 |
|---|---|---|---|---|
| 1906 | 9 | 0 | 0 | 0 |
| 1907 | 4 | 0 | 0 | 0 |
| 1908 | 15 | 1 | 6.66 | 0 |
| 1909 | 9 | 1 | 11.11 | 0 |
| 1910 | 13 | 0 | 0 | 0 |
| 1911 | 14 | 0 | 0 | 0 |
| 1912 | 13 | 0 | 0 | 0 |
| 1913 | 9 | 0 | 0 | 0 |
| 1914 | 17 | 0 | 0 | 0 |
| 1915 | 25 | 2 | 8.00 | 1 |
| 1916 | 19 | 3 | 15.78 | 2 |
| 1917 | 13 | 2 | 15.38 | 1 |
| 1918 | 30 | 1 | 3.33 | 0 |
| 1919 | 30 | 3 | 10.00 | 2 |
| 1920 | 25 | 3 | 12.00 | 2 |
| 1921 | 39 | 4 | 10.25 | 3 |
| 1922 | 46 | 5 | 10.87 | 3 |
| 1923 | 50 | 8 | 16.00 | 6 |
| 1924 | 35 | 4 | 11.42 | 4 |
| 1925 | 49 | 7 | 14.28 | 7 |
| 1926 | 36 | 4 | 11.11 | 4 |
| | 498 | 48 | | 35 |

During this second series of cases the following methods were used: (1) radical surgery; (2) radium therapy; (3) surgery preceded or followed by irradiation; (4) roentgen therapy.

TABLE 5.—*Clinical Classification of Patients*

| Classification | 1906–1916 | 1917–1926 |
|---|---|---|
| Group 1 | 11 | 24 |
| Group 2 | 15 | 31 |
| Group 3 | 37 | 70 |
| Group 4 | 82 | 187 |
| Recurrence in stump or vagina | 1 | 35 |
| Unclassified | 1 | 4 |
| Total | 147 | 351 |

TABLE 6.—*Analysis of Cures, 1906-1916 (No Radium Available)*

| Clinical Classification | Number of Cases | Number of Cures | Per Cent of Cures (Absolute) | Number of Operations | Per cent Operative Cures |
|---|---|---|---|---|---|
| Group 1 | 11 | 3 | 27.2 | 10 | 30 |
| Group 2 | 15 | 4 | 26.66 | 12 | 36.36 |
| Group 3 | 37 | 0 | 0 | 9 | 0 |
| Group 4 | 82 | 0 | 0 | 4 | 0 |
| Stump of cervix | 1 | 0 | 0 | 0 | 0 |
| Unclassified | 1 | 0 | 0 | 0 | 0 |
| | 147 | 7 | | 35 | |

Seven cures of 35 operated cases = 20 per cent relative operative cures.

1. As previously stated, radical surgery was by the Wertheim or the Schauta type of operation.

2. Radium was not at first used in a standardized method. The radium element (150 mg.) was used in the form of bare needles, and also with screening of rubber, lead, brass and/or dental wax. It was used in

varying dosages; as low as 2,200 milligram hours and as high as 8,000 milligram hours were used in an attempt to effect a cure. Radon also was used during this time with varying success. It was not until the end of the period of this paper that a definite method of radium therapy came into use.

Table 7.—*Five Year Cures, All Treatments, 1917-1926*

| Clinical Classification | Number of Cases | Number of Cures | Per Cent of Cures (Absolute) |
|---|---|---|---|
| Group 1 | 24 | 13 | 54.17 |
| Group 2 | 31 | 10 | 32.25 |
| Group 3 | 70 | 9 | 12.85 |
| Group 4 | 187 | 6 | 3.20 |
| Stump of cervix | 35 | 3 | 8.57 |
| Unclassified | 4 | 0 | 0 |
| | 351 | 41 | |

3. Radium and radical surgery were used in a few cases *in combination.* When a cure or failure was encountered in the use of this combined form of treatment, the method which was deemed by careful examination to be the cause of success or failure was so credited. This was done on microscopic examination of the tissue removed before or at the time of the second treatment. For example, a patient having received a preliminary dose of radium was operated on at a later date. Microscopic examination of the cervix showed an active carcinoma. This patient remained well for five years, and the cure was listed as an operative one.

Table 8.—*Radium or Operative Cures, 1917-1926* *

| Clinical Classification | Number of Operations | Number of Cures | Per Cent of Operative Cures | Number Irradiated | Number of Cures | Per Cent of Radium Cures |
|---|---|---|---|---|---|---|
| Group 1 | 15 | 9 | 60.00 | 9 | 4 | 44.40 |
| Group 2 | 10 | 5 | 50.00 | 21 | 5 | 23.81 |
| Group 3 | 4 | 0 | 0 | 66 | 9 | 13.48 |
| Group 4 | 2 † | 1 † | 50.00 | 181 | 5 | 2.76 |
| Stump of cervix | 0 | 0 | none treated | 35 | 3 | 8.57 |
| | 31 | 15 | 48.38 | 312 | 26 | = 8.33 |

Operated ........ 31
Radiated ......... 312
343
No radium or operation (palliative-acetone, etc.) ..... 8
351

Cures:
Operative.. 15 out of 31 cases = 48.38%
Radium.... 26 out of 312 cases = 8.33%
41 out of 343 cases = 11.96% of all cases treated with radium or operation.

---

* Operations were either Wertheim or Schauta or radical cauterization (Byrne).
† Cautery.

4. High voltage roentgen therapy as a supplement to other forms of treatment was used in a minority of the cases. Palliative results in the control of bleeding, discharge and pain were obtained. In the past five years more intensive and systematic roentgen therapy has been given as an auxiliary to radium therapy and to surgery.

Table 9 demonstrates the relation of age to cure. It is seen that the very young women, of whom there were eighteen below the age of 30, have indeed a poor prognosis, as our percentage of 5.55 would tend to show. Our greatest number of five-year cures are seen in the age groups of 30 to 35 and 55 to 60. Of the patients coming to us after the age of 70 there were no five-year cures.

The end-results of all radical operations for carcinoma of the cervix over the entire period of this survey are seen in table 10. The 20 per cent primary operative mortality seems rather high, but at the present time, with greater care in the selection of cases, better preoperative preparation and preliminary radium treatment, this has been greatly reduced. A total of sixty-six cases shows a five-year cure rate of 33 per cent. These figures include fourteen inoperable cases in which operation was performed prior to 1917. Were it possible to omit these cases from our figures, a much higher five-year cure rate would result with a slightly lower primary operative mortality. In compiling this table it was noted that 75 + per cent of all patients treated with radium were dead within one year and 90 + per cent were dead within twenty-four months. A patient who has been treated with radium and who survives two years seems to have a very good chance of remaining free from recurrence for at least five years. This summary also demonstrates the low operability rate of all patients seen in this clinic. The absolute operability rate, including the 136 untreated cases, is 12.7 per cent; the relative figure computed only with respect to the number of treated patients is 16.27 per cent. These figures once more emphasize the unfavorable quality of the material that congregates in a cancer hospital.

Table 9.—*Relation of Age to Cure*

| Age | Cures | Cases | Per Cent of Cure |
|---|---|---|---|
| 20 to 30 | 1 | 18 | 5.55 |
| 30 to 35 | 6 | 45 | 13.32 |
| 35 to 40 | 6 | 79 | 7.59 |
| 40 to 55 | 23 | 225 | 10.22 |
| 55 to 60 | 9 | 63 | 14.28 |
| 60 to 70 | 3 | 45 | 6.66 |
| 70 to 90 | 0 | 13 | 0 |
| | 48 | 488 | |
| Ages unknown | .. | 10 | |
| | | 498 | |

A study of the cases revealed the fact that 96 per cent of all patients seen were multiparous. This figure is larger than one would expect in a similar group of women of the same age not having cancer and adds to the evidence that the irritation of the cervix due to pregnancy with subsequent dilatation of the cervix is one of the factors influencing the frequency of the neoplasm at this site.

Irradiation was repeated in twenty-three cases at periods varying from four months to two years after the completion of the primary therapeutic course. Three of these patients survived the five-year period. This is practically double the rate obtained in those cases in which irradiation was not repeated (13.1 per cent compared to 7.7 per cent). In the past three years, increasing numbers of patients have been irradiated more than once with satisfactory results.

Table 10.—*Radical Operations, 1906-1926*

| | Number | Per Cent |
|---|---|---|
| Lost after leaving hospital | 13 | 20 |
| Died postoperatively | 13 | 20 |
| Alive 5 years or more | 22 | 33 |
| Alive 4 years | 2 | 3 |
| Alive 3 years | 4 | 6 |
| Alive 2 years | 8 | 12 |
| Alive less than 2 years | 4 | 6 |
| | 66 | 100 |

Radium cases:
90+% dead within 24 months
75+% dead within 12 months
But 81 cases of 634 seen were classified as operative (groups 1 and 2), an operability rate of but 12.74%

Material for the study of the index of malignancy as described by Broders was found available in the pathologic files in more than 300 cases from 1906 to 1926. The details of this histologic study will be published at a later date.

### SUMMARY

1. This paper is based on 498 cases of primary carcinoma of the cervix treated from 1906 to 1926 at the Barnard Free Skin and Cancer Hospital.

2. The low percentage of cure may be in part ascribed to the geographic location of this clinic, with the resulting difficulties in the follow up of patients, and also by the large percentage of far-advanced cases presenting themselves for treatment.

3. Prior to the use of radium, but 4.76 per cent of the patients survived a five-year period. After the use of radium was begun, 11.67 per cent of the patients survived a five-year period.

4. The educational campaign instituted by the American Society for the Control of Cancer has definitely increased the number of patients applying to our hospital, but the percentage of early cases has not greatly increased (from 11 per cent to 16 per cent).

5. The repetition of irradiation is of considerable importance and should increase the survival rate. This feature is dependent on an efficient social service follow-up system to insure frequent systematic examinations to detect recurrences at the earliest possible time. This service can function efficiently, as is borne out by the fact that no case in this service has been lost in the past three years.

6. In certain cases a combination of surgery and irradiation would seem definitely indicated.

7. Radium and roentgen therapy offer the only hope of cure in cases of clinical group 3 and group 4 carcinoma of the cervix.

8. Radical surgery proved superior to radium therapy in establishing a cure in patients in whom the carcinoma was apparently confined to the cervix. In groups 1 and 2 of the period 1917-1926, 56 per cent of twenty-five operated on were cured, whereas only 30 per cent of the thirty irradiated remained well over five years. Furthermore, the operative results showed greater permanence after the five-year period than did the irradiated patients. For these reasons I believe that our results indicate that radical surgery still offers the greater hope of cure in early carcinoma of the cervix.

**The Eosinophil and Basophil Cells in the Pituitary.**—Evans and Simpson have been able to isolate from the eosinophil cells a hormone which is concerned with growth, and another from the basophil cells which is concerned with sexual development. Moreover, there is a definite antagonism between them, the growth hormone being capable of completely nullifying the other if both are simultaneously injected. That growth precedes sexual maturity is presumably due to the early predominance of the growth hormone. When the basophil cells are about to assert themselves over the eosinophil cells, puberty occurs. The association between the eosinophil cells and growth is indicated by the coincidence of eosinophilous adenomas with gigantism or hemihypertrophy, if they develop before the epiphyses join up, and with acromegaly if they develop subsequently. Gigantism is sometimes quite partial—as in one finger. Beware of removing such local gigantisms; the operation has been followed by a gigantic growth of the whole limb. This has an interesting bearing on Susman's recent hypothesis as to the influence of overactivity of the anterior lobe in the causation of malignant disease.—Brown, W. L.: Remarks on the Endocrines and Some Associated Psychoneuroses, *Brit. M. J.*, Feb. 6, 1932.

# “ABORTIVE” POLIOMYELITIS

JOHN R. PAUL, M.D.
ROBERT SALINGER, M.D.
AND
J. D. TRASK, M.D.
NEW HAVEN, CONN.

To Wickman,[1] credit is usually and justly given for the first adequate description of so-called abortive poliomyelitis, although a few years previously reference had been made to the existence of variant forms of the disease.[2] It would seem, however, that present-day usage of the somewhat unfortunate term abortive poliomyelitis does not embrace all the manifestations of the disease that Wickman had in mind. He included four varieties of poliomyelitis of the abortive type: (1) cases running the course of a general infection; (2) cases in which signs of meningeal irritation were especially prominent ("pseudomeningism"); (3) cases accompanied by distinct tenderness ("pseudo-influenzal"), and (4) cases with disturbances of the gastro-intestinal tract. He believed that abortive cases, representing any or all of his four types, made up a considerable proportion of all the cases in any epidemic of poliomyelitis but that their exact ratio could not be determined.

The same general concept has been held by Draper,[3] who, in emphasizing the dual phases of clinical poliomyelitis, points out that in the first phase the cardinal symptoms may be those of a gastro-intestinal upset, tonsillitis or malaise, and that from 50 to 80 per cent of the total incidence of the disease may be limited to this phase. However, such nondescript symptoms as those which characterize the first phase do not present a clinical picture which may be readily identified, and perhaps this is the reason that many physicians seem unwilling to make a diagnosis of either poliomyelitis or abortive poliomyelitis in the absence of meningitic or myelitic involvement. In any event, the question of uncertainty of diagnosis has precluded the inclusion of such cases in statistics on poliomyelitis,[4] although it is needless to point out that, if the disease is thus limited, such a concept will enormously influence views not only on its epidemiology but also on its fundamental nature. Furthermore, although there are occasional early instances of the demonstration of specific protective bodies in the blood of patients who had sustained an attack of abortive poliomyelitis,[5] its status as a concrete entity has been somewhat shaken by a recent study by Kramer and Aycock.[6] Their results tend to show that a group of children who had passed through minor illnesses (probably comparable to Wickman's abortive types), which occurred coincidentally

with an epidemic of poliomyelitis, failed to show a higher percentage of specific protective bodies in their blood than did two control groups of children.

Our own studies, which were made in New Haven during the summer of 1931, deal with certain aspects of the same general problem: namely, What is abortive poliomyelitis? and How important is it?

Both questions were rather vividly impressed on us by the difficulties in diagnosis experienced during the recent epidemic. For practical purposes some diagnostic criteria seemed necessary and these gradually resolved themselves into the following features which were accepted as positive evidence of poliomyelitis: (*a*) the development of paralysis in association with the usual signs of the disease, with or without the association of positive manifestations of the spinal fluid; and (*b*) the presence of a pleocytosis (i. e., more than 12 cells), or a definite increase of globulin in the spinal fluid, in association with the usual signs of the nonparalytic form of the disease. Such criteria eliminate innumerable cases characterized only by sore throat, fever, vomiting or headache with or without mild stiff neck which accompany an epidemic of poliomyelitis. Obviously the accepted criteria are incomplete, but it is equally obvious that the question as to where to draw the line is difficult.

In an effort to answer some of the problems of definition in this disease, studies on the symptomatology and particularly the laboratory observations were carried out in a series of suspected cases. An analysis of these results will appear in another publication.[7] In brief, it was found that the usual diagnostic procedures including lumbar puncture were inadequate to answer the question as to whether or not we were dealing with poliomyelitis in many borderline cases. Consequently, resort was had to other methods of approach furnished by the presence of an epidemic. The first object in our epidemiologic studies was to determine the incidence of minor illnesses[8] in association with cases of bona fide poliomyelitis. Two lines of approach were used: (1) family studies and (2) community studies.

## I. FAMILY STUDIES ON THE INCIDENCE OF MINOR ILLNESSES OCCURRING COINCIDENTALLY WITH POLIOMYELITIS

Following methods which have been developed by Opie and his co-workers in studying the spread of tuberculosis through families,[9] and which two of us have similarly employed in rheumatic fever,[10] data were assembled and charted in 222 families, from each of which had come one or more bona fide cases of poliomyelitis. It has been generally observed that there is but little tendency for poliomyelitis to spread in families, and in the epidemic of 1916 only 4.3 per cent of 8,634 families attacked in New York City were reported as having more than one case.[11] Furthermore, there are indications that the majority of multiple cases (80 per cent) are of common source appearing more or less contemporaneously with one another.[12] By taking advantage of the latter fact we have subjected families to a period of intensive observation on or about the time at which a known case of poliomyelitis appeared, having as our particular object the acquisition of first hand observations or of records, not only of other familial examples of recognizable poliomyelitis during this period, but also examples of any type of illness, however mild.[13]

In the course of this work it immediately became apparent that in these families the illnesses, other than those reported to the local board of health as examples of poliomyelitis, divided themselves into three groups: (A) an acute, febrile episode, characterized by sore throat, headache and vomiting, which frequently lasted only twenty-four or thirty-six hours but as a rule left the child feeling below par for several days; (B) mild upsets referable to the upper respiratory or gastro-intestinal tract, such as colds without fever or diarrhea; (C) recognizable clinical entities such as pertussis and ivy poisoning, with which we had little concern. It has been difficult to draw a sharp line between groups A and B, but the attempt has been made to restrict our use of the term characteristic minor illness only to those cases fulfilling the criteria mentioned under group A. In one of our statistical compilations, group B has, however, been included as a separate category (as in figure 3).

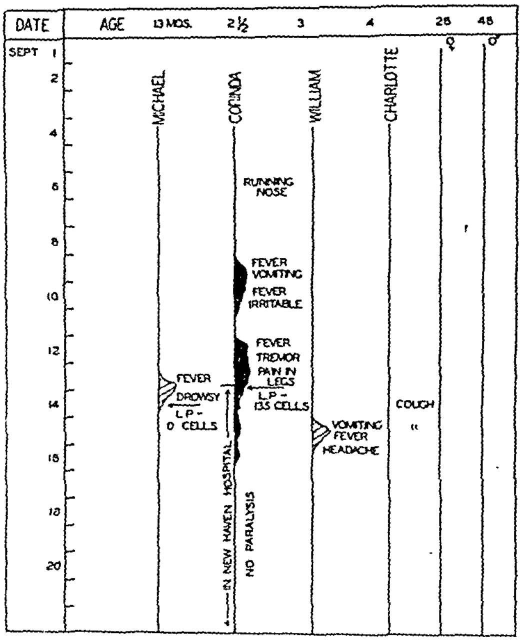

Fig. 1.—A schematic diagram of family Rn. The vertical lines indicate different members of the family; their ages appear at the top. The solid black areas indicate the onset and course of a poliomyelitic infection in one child; the shaded areas indicate the course of minor illnesses. The initials L. P., surmounted by an arrow, denote the time at which lumbar punctures were performed.

A sample family appears in figure 1. Here it will be seen that in a family with four children there occurred one case of poliomyelitis, which was followed closely by two cases of characteristic minor illness in two other children; in one of the latter, the most prominent symptom was fever, and in the other, fever, vomiting and headache. In the youngest child the symptoms were sufficiently suggestive to warrant a diagnostic lumbar puncture, which proved negative. There are enough examples in the literature of family epidemics similar to that shown in figure 1 (notably those appearing in the reports of Taylor and Amoss [14] and Aycock and Luther [15]) to suggest that this situation is not a rare one, but it was one of our main purposes to estimate the frequency with which it actually occurred. For these estimates, data and charts similar to that shown in figure 1 were prepared in all of our 222 families. They revealed that the situation shown in figure 1 is quite common. Actually it was found that, in families in which one or more cases of poliomyelitis arose, illness similar to that shown by Michael and William in figure 1 appeared among the other children in the various percentages shown in table 1.

[8] We have employed the term minor illness in subsequent sections of this article rather than "abortive poliomyelitis." Both are vague, but many of the minor illnesses in which we have been interested present symptoms so remote from that of "abortive poliomyelitis" in the usually accepted sense that, until surer ground has been reached, the term minor illness seems preferable.

[13] We are indebted to Drs. J. L. Rice and D. M. Lewis of the Department of Health, City of New Haven, for the privilege of studying these families

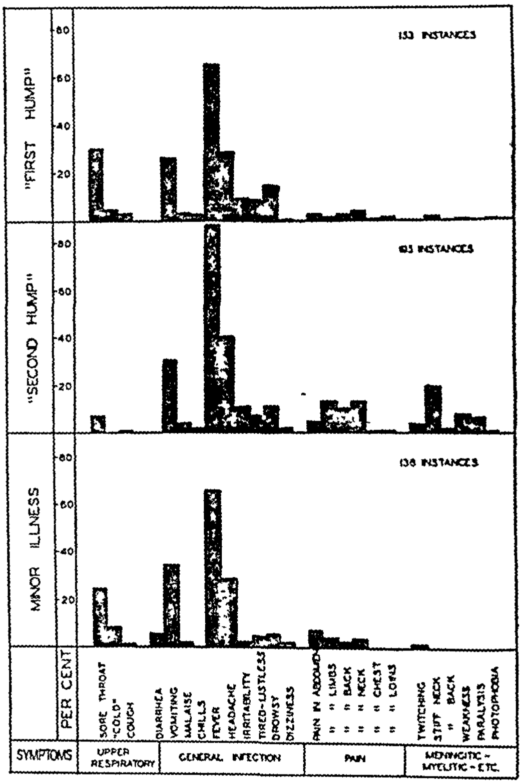

Fig. 2.—A diagrammatic representation of the percentage incidence in which different early symptoms were recorded in the histories of patients in the first and second phases or "hump" of poliomyelitis, as compared with the symptoms appearing in characteristic, familial, minor illnesses.

A comparison between the high rate of incidence of these characteristic minor illnesses can be made with the results obtained from control children representing families from which no case of poliomyelitis had come. Comparable data were obtained on these control families during the epidemic period.

As we have already mentioned, these minor illnesses present a fairly characteristic, although by no means specific, clinical picture, and, furthermore, the spinal fluid obtained from lumbar punctures performed early in the illness generally fails to show abnormal conditions. In an analysis of their symptomatology, we have compared them with the two clinical phases of poliomyelitis.[16] A graphic representation of this analysis, based entirely on data obtained from the patients' histories, appears in figure 2. As is well known and as has been particularly emphasized by Draper,[3] the first phase or "hump" in the so-called dromedary type of the disease is, when present, usually characterized by symptoms of a general infection, and the second "hump" by those of infection with myelitic involvement.

TABLE 1.—*Percentages of Children with Characteristic Minor Illness*

| | | Age | | | | |
|---|---|---|---|---|---|---|
| | | Under 1 | 1-4 | 5-9 | 10-14 | 15-19 |
| 222 Poliomyelitis Families | Number of children in each age group | 23 | 109 | 138 | 107 | 73 |
| | Percentage with characteristic minor illness (group A)* | 12 | 39 | 32 | 17 | 7 |
| 60 (control) Nonpoliomyelitis Families | Number of children in each age group | 10 | 54 | 90 | 76 | 39 |
| | Percentage with characteristic minor illness (group A)† | 0 | 10 | 8 | 0 | 0 |

* Only those examples of illness are included which appeared within three weeks of the time of onset of a familial case of poliomyelitis.

† This includes illness which appeared within a period of six weeks during the time the local poliomyelitis epidemic prevailed.

In our analysis of the symptoms of 195 cases of poliomyelitis, it will be seen that first phase symptoms and early symptoms of the second phase differed from each other essentially in two respects: (*a*) by the increased presence of symptoms of the upper respiratory tract, particularly sore throat in the first "hump," and (*b*) by the presence of signs pointing to meningitic or myelitic involvement in the second. The symptomatology of the coincidental intrafamilial minor illnesses corresponds somewhat more closely to the first "hump" in that here again symptoms of involvement of the upper respiratory tract, such as sore throat, were prominent, and obviously signs of meningitic and myelitic involvement were practically absent. The inference naturally arises, therefore, as to whether these *minor illnesses* actually represent the first phase of poliomyelitis, as Draper believes, and it would seem that on a symptomatologic basis most of the evidence

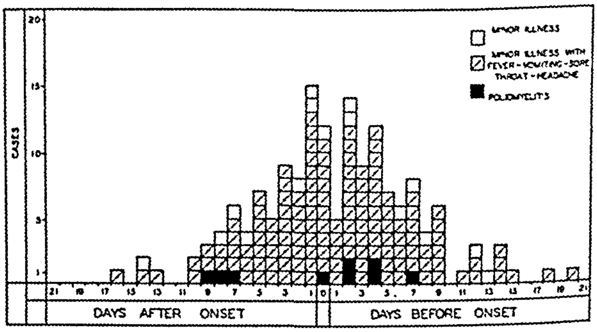

Fig. 3.—Time relationships of the onset of multiple familial cases of poliomyelitis compared with similar relationships of the onset of characteristic familial minor illnesses. Squares with a diagonal represent group A; open squares, group B.

[15] Aycock, W. L., and Luther, E. H.: The Incubation Period of Poliomyelitis, J. Prev. Med. **3**: 103 (March) 1929.

[16] In an unpublished clinical analysis of 195 patients with poliomyelitis, admitted to the New Haven Hospital during the summer of 1931, those showing the characteristic double phase represented 54 per cent of the series.

would point this way. However, this issue is slightly clouded by the fact that in our series of minor illnesses here again two phases or periods of illness were observed in about 10 per cent of the cases. All that can be said at the moment, therefore, is that our data on this point suggest that generally the symptomatology of the minor illness mimics that of the first phase of poliomyelitis.

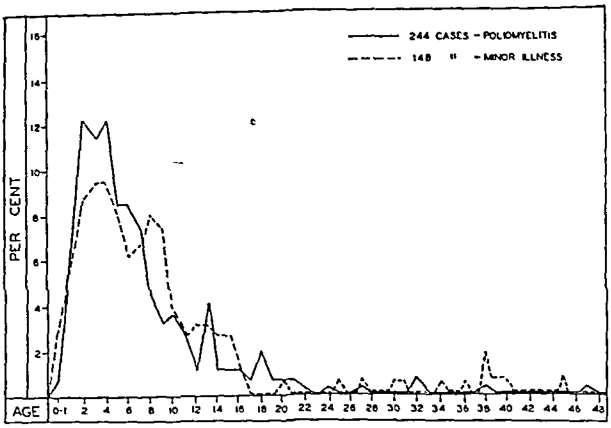

Fig. 4.—The age distribution of cases of poliomyelitis, occurring locally during the 1931 epidemic, as compared with the age distribution of characteristic minor illnesses which occurred in the families of these patients.

In figure 3 is shown the relatively close relationship in time of onset which these characteristic minor illnesses (group A), and also other less characteristic minor illnesses (group B), bore to the day of onset (zero day in fig. 3) of a familial case of poliomyelitis.[17] Similar time relationships between multiple intrafamilial cases of poliomyelitis are also shown. It is evident, therefore, not only that multiple familial cases of poliomyelitis appear more or less contemporaneously but also that minor illnesses appear more or less contemporaneously with familial cases of poliomyelitis.

Another comparison which may be made is that of the age groups affected by poliomyelitis on the one hand, and by these characteristic minor illnesses on the other. In figure 4 the age incidence of 244 cases of poliomyelitis seen in the New Haven Hospital during the summer of 1931 has been charted, together with the age incidence of 148 instances of contemporary minor illness occurring in the families of these patients. The similarity of the two curves is quite striking.

## II. COMMUNITY STUDIES ON THE INCIDENCE OF MINOR ILLNESS OCCURRING COINCIDENTALLY WITH POLIOMYELITIS

Following the leads afforded by the family observations, three more or less isolated communities adjacent to New Haven were chosen for intensive study. The criteria employed in selecting the communities were that (*a*) at least two cases of poliomyelitis had occurred in the community; (*b*) the geographic limits of the community could be defined; (*c*) the size of the total susceptible (juvenile) population could be determined, and (*d*) all the families in the community could be studied.

Data from one of our community studies appear in figures 5 and 6. In figure 5 a rough diagrammatic map of the situation is shown. The community consisted of a group of summer cottages situated on the shore of Long Island Sound which were, fortunately, occupied by very intelligent and cooperative families.[18] The events that transpired in this community during the summer of 1931 are shown in figure 6; all the juvenile (i. e., under 16) members of the group have been portrayed as vertical lines, on which illnesses have been recorded by the symbols used in figure 1. It will be seen that the population was not fixed, in that families were constantly moving in or out. Late in July and early in August several cases of mild illness characterized by sore throat, fever, vomiting and headache appeared among the children, but although there was considerable apprehension by attending physicians and the community itself as to whether the illnesses might be poliomyelitis, none of them showed symptoms from which a definite diagnosis could be made, and so they were labeled "summer grip."

On August 20, a child from family 9, who had left the summer colony the week before, developed poliomyelitis, and shortly thereafter three other cases appeared among members of the colony in rather rapid succession. Meanwhile, the "summer grip" continued, although three out of five of the children who contracted it during September had arrived in the community subsequent to August 15. In all, therefore, out of forty-one children in the community there were twenty-nine instances of acute illness between July 30 and September 22. Four of these illnesses proved to be poliomyelitis. Many of the others merely consisted of fever, headache, and vomiting of one day's duration, but some were of several days' duration; others presented two distinct phases, and not a few offered real problems in the differential diagnosis of poliomyelitis. Practically the same experiences were encountered in our two other community studies; and in all three the ratio of cases of poliomyelitis to minor illnesses proved to be practically the same, namely, 1 : 6. If one were to

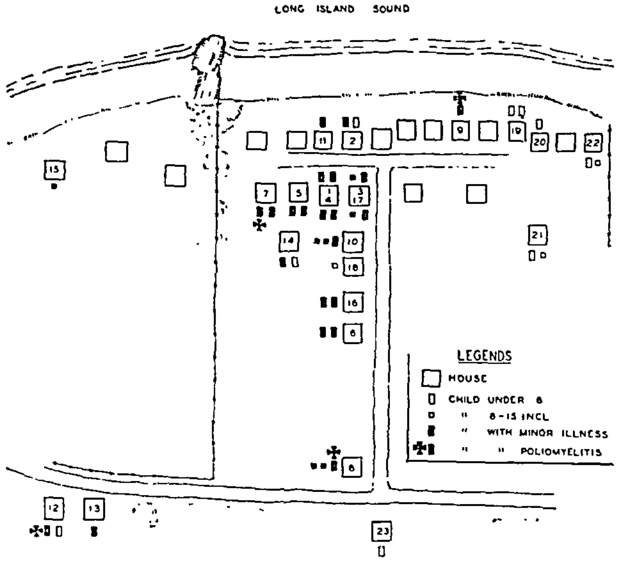

Fig. 5.—A diagrammatic map of community 3 in which are shown the total juvenile population and the number who suffered from minor illnesses or from poliomyelitis between July 25 and Sept. 25, 1931.

---

[17] In determining the time of onset of a case of poliomyelitis we have designated the first appearance of symptoms, including first phase symptoms when present, as the first day of the disease.

[18] We are indebted to Dr. Millard Knowlton of the Department of Health, State of Connecticut, and to Dr. M. P. Rindge, district health officer of Madison, Conn., for the privilege of studying this community.

be so bold as to suggest that these minor illnesses were actually mild forms of poliomyelitis one would be led to the conclusion that, under the circumstances described, mild or "abortive" poliomyelitis occurred six times as frequently as did poliomyelitis in which the diagnosis could be made with certainty according to present-day criteria.

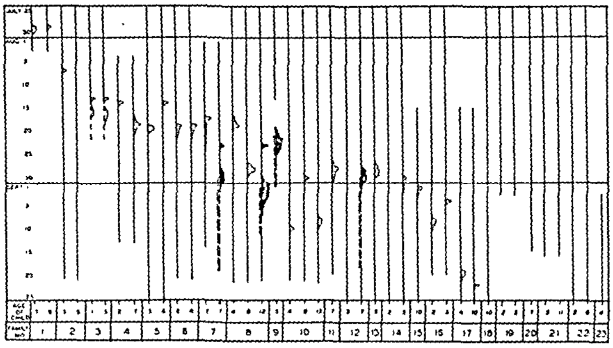

Fig. 6.—The juvenile population of community 3 The onset and course of poliomyelitis and characteristic minor illnesses is denoted by symbols similar to those used in figure 1.

A summary of the data shown thus far from our family and community studies merely goes to show that circumstantial evidence has been raised, pointing to a close relationship between the characteristic minor illness on which we have laid so much stress, and poliomyelitis. To test this circumstantial evidence from another angle, recourse was had to experimental methods.

### DEMONSTRATION OF THE VIRUS OF POLIOMYELITIS IN ORAL SECRETIONS FROM CASES OF MINOR ILLNESS

It is an established fact that the poliomyelitic virus may be detected by the monkey inoculation test, in washings from the throats of acute cases of poliomyelitis,[19] but rarely from human throats under other conditions.[20] To our knowledge there are two examples of its detection in pooled nasopharyngeal washings taken from healthy familial contacts (Flexner, Clark and Fraser,[21] Kling and Pettersson [22]).[23] An important observation which has direct bearing on our studies is that of Taylor and Amoss,[14] who were successful in isolating the virus from two members of a family of four children in which three, or probably four, cases of poliomyelitis occurred. One of the successful instances was obtained from a child five days before she came down with a mild attack of the disease; the other from a child four days subsequent to the development of symptoms which recall those of our characteristic minor illnesses. The number of attempts to repeat the previously quoted observation is unknown, but it is evident from the small number of successful reports of the isolation of the virus from patients not suffering from bona fide poliomyelitis that it is not easy, and it was with rather meager hopes of success that our experiments were initiated.

The technic used was varied from time to time, and our two successful results were attained with unconcentrated as well as with concentrated washings.

The patient was instructed to gargle the throat with from 25 to 125 cc. of sterile water, or it was washed through the nasopharynx by means of a nasal catheter. The washings were collected in a flask containing glass beads, which were shaken vigorously for fifteen minutes. This material was then usually concentrated by vacuum distillation at 37 C. for a period not exceeding six hours (by this procedure we were seldom able to reduce the washings to less than a fourth of their original volume). To the concentrated washings 0.5 per cent phenol was added and the material allowed to stand for half an hour, in order to reduce the number of bacteria. This step in the procedure was employed in preference to filtration, as it has been shown that, in spite of the bactericidal properties of phenol, poliomyelitic virus may remain active in 0.5 per cent phenol for many months.[24] Between 0.5 and 1.0 cc. of the phenolized material was then inoculated intracerebrally into the brain of an etherized monkey. Material thus treated and inoculated intracerebrally into twenty monkeys gave rise to pyogenic infection, or brain abscess, once. Rectal temperatures were taken twice daily on all monkeys thus inoculated, for a period of three weeks. If suspicious or definite signs of paralysis developed, the animal was killed and an autopsy was done. Practically all the surviving monkeys in this

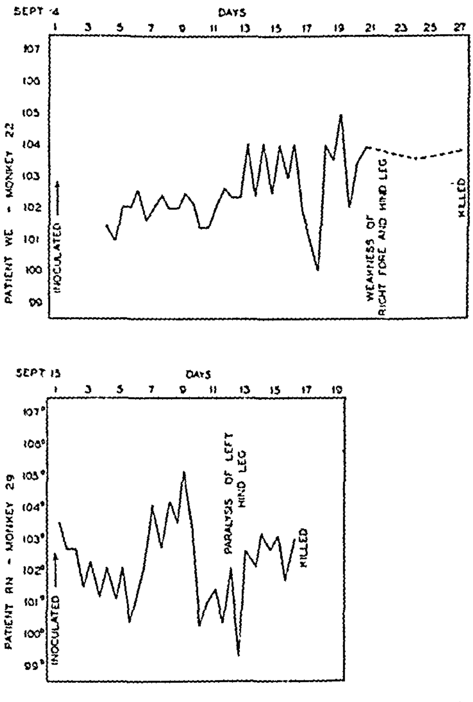

Fig. 7.—Temperature curves shown by the two monkeys (22 and 29) in which the experimental disease was produced as a result of the intracerebral inoculation of nasopharyngeal washings from two cases of minor illness.

[22] Kling, C., and Pettersson, A.: Keimträger bei Kinderlähmung, Deutsche med. Wchnschr. **40:** 320 (Feb. 12) 1914.

[23] We have recently gone over the well known work of Kling, Pettersson and Wernstedt (*The Presence of the Microbe of Infantile Paralysis in Human Beings: Investigation on Epidemic Infantile Paralysis, Report from the State Medical Institute of Sweden to the Fifteenth International Congress on Hygiene and Demography, Washington, D. C. 5, 1912) who reported the detection of poliomyelitic virus from a rather high percentage of examples of minor illness and from healthy contacts.* The criteria which these authors used for the detection of the virus are so different from those in use to-day that it is difficult to evaluate their results.

[24] Amoss, H. L.: Virus Diseases of Man as Exemplified by Poliomyelitis. Filterable Viruses, edited by T. M. Rivers, Baltimore, Williams & Wilkins Company, 1928.

series were subsequently tested and found susceptible to infection with a known strain of poliomyelitic virus.[25]

Oral washings from twelve examples of minor illness, three cases of poliomyelitis and four contacts, were treated in the manner described. In all, twenty monkeys were inoculated. As already stated, one monkey that had been inoculated with material obtained from a supposed contact succumbed with a brain abscess on the sixth day and consequently has not been included in the series.

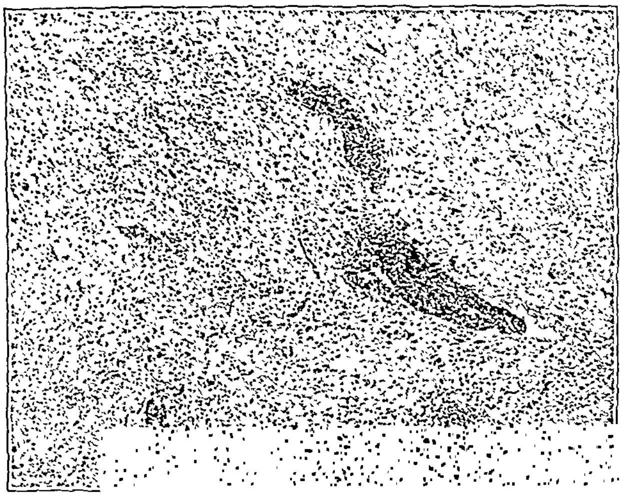

Fig. 8.—Section showing characteristic lesions of poliomyelitis in the spinal cord of monkey 22; × 55.

The results appear in table 2. Here it will be seen that from twelve tested cases of minor illness the virus was detected in two and that both of the positive results were obtained with washings taken on the first and second days of the disease, representing two successful attempts out of five trials during this early period. A further commentary which also seems important is that. as these minor illnesses are often very brief, two of the children were practically without symptoms on the second day and were up and playing at the time the irrigation was done. In neither of these cases was the virus detected. Therefore, of the three cases tested within forty-eight hours of the onset of the disease and in which symptoms still persisted, two furnished the virus by the methods employed.

Table 2.—*Summary of Results of Monkey Inoculations with Oral Washings*

| | Day of Illness or Contact on Which Washing Was Done | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 1 | 2 | 3 | 4 | 5 | 6-10 | 11-15 | Total |

| Number of positive results | 0 | .. | .. | .. | .. | .. | .. | 0 |

* The day of contact represents the day numbered from the onset of the last case to which the subject was intimately exposed.

The two patients in whom the virus was detected have already figured in previous sections of this paper. One was Michael, aged 13 months, shown in figure 1. It will be recalled that he was suspected of having poliomyelitis but that this suspicion was allayed by the presence of a negative lumbar puncture and the rapid disappearance of symptoms after twenty-four hours. The second was a child, aged 5 years, who appears as the oldest juvenile member of family 16 in figure 6.

## EVIDENCES OF POLIOMYELITIS IN THE MONKEYS

Besides the development of characteristic paralysis, temperature readings have proved valuable in detecting the experimental disease in the monkey. It will be recalled that the normal temperature range of rhesus monkeys is about 102 to 103.

Kramer, Hendrie and Aycock[26] have recently described the characteristic temperature curve which appears in monkeys inoculated intracerebrally with the virus of poliomyelitis. They call attention to the fact that there may be an immediate brief rise in temperature, but this usually does not last beyond the first twenty-four hours. The incubation period or period of "normal" temperature prior to the onset of the true experimental disease generally lasts from four to eight days but at times as long as from eighteen to twenty-one days. With the onset of the disease there is an abrupt rise in temperature reaching 104 to 107. Fever may persist from one to three days before the onset of the usual recognizable symptoms, such as paralysis. With the appearance of these symptoms the temperature is already declining, and when paralysis is extensive there may be a pronounced drop to subnormal values.

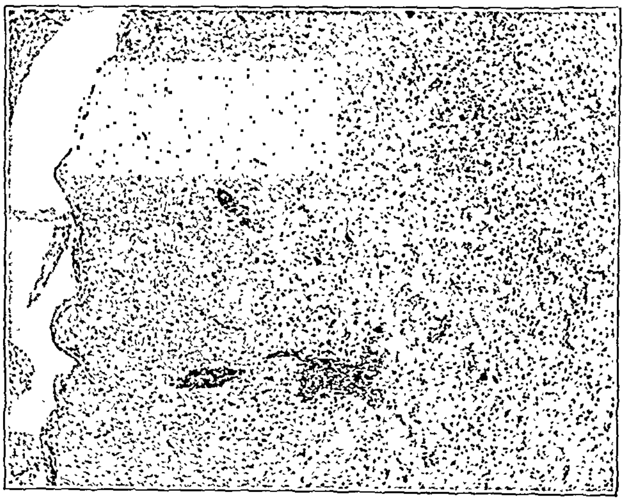

Fig. 9.—Section showing characteristic lesions of poliomyelitis in the spinal cord of monkey 29; × 55.

In figure 7 are shown the temperature curves of the two monkeys (22 and 29) in which the experimental disease was produced by inoculation of washings from two of our cases of minor illness. It will be seen that they conform to the picture that has just been described. In monkey 22 (patient We.) the incubation period was about twelve days and the development of paralysis was never particularly extensive. In monkey 29 (patient Rn.), the incubation period was six days, the febrile reaction brief, the temperature quite high, and paralysis of one leg marked. Both monkeys were killed five days after the development of definite paralysis. The autopsy revealed typical lesions in the spinal cord of each animal (figs. 8 and 9). Both of the strains of virus thus isolated were subsequently passed to other monkeys. A more detailed description of this aspect of our work will appear in another publication.[27]

---

[25] We are indebted to Dr. E. R. Weyer and to Dr. W. H. Park of the Bureau of Laboratories, Department of Health, City of New York, for the standardized strain of poliomyelitic virus which we used in retesting these monkeys.

## COMMENT

Evidence has been brought forward in this paper, more or less corroborating the experiences of many previous observers, which shows that accompanying an epidemic of poliomyelitis there appear many examples of illness with symptoms not unlike those of incipient poliomyelitis. Emphasis has been laid on the surprisingly high percentage of exposed children who present these mild symptoms and the similarity that exists between the age distribution of this group and the age distribution of those who coincidentally develop recognizable poliomyelitis. Estimates with regard to the incidence or ratio of these minor illnesses to cases of poliomyelitis have been made in three communities and in each it was found that the former were approximately six times as frequent as the latter. From two children with these minor illnesses the virus of poliomyelitis has been detected in the throat, a finding which taken in conjunction with the other observations suggests that a common causal relationship exists between such illnesses and the usually accepted entity of poliomyelitis. We are aware, however, of the possibility that these individuals might have been mere carriers of the virus and, as such, not necessarily suffering from infection with it. The consistency with which negative results are encountered among contacts and also among those who had had a minor illness but were convalescent would, however, militate against this view.

The question naturally arises: Are all these instances of minor illness, however mild they be, actually examples of so-called abortive poliomyelitis? If such is the case, the previously unsuspected high incidence of the disease might explain the ease with which it spreads, as well as the mass immunization of most adult populations to the disease; an immunization which thus becomes clinical rather than subclinical in spite of recent evidence to the contrary.[6] It seems evident, however, that the reason that suspected variant forms of the disease, which have been so often described in conjunction with epidemics of poliomyelitis, have been so belittled is that there is practically nothing specific about them. There is no obviously apparent means of recognizing them, simulating as they do so many minor infections, and as a matter of fact we seem less able to recognize them today than did Wickman almost thirty years ago. The question is an old and difficult one and we have merely raised it without presenting a practical solution; but in the face of so much suggestive evidence the crux of the problem as to whether some or all of the minor illnesses which we have listed as characteristic of those seen in the epidemic period are, in actuality, poliomyelitis would seem to be one of definition. Certainly there seems little doubt that some of the minor illnesses we have described are related to orthodox poliomyelitis. If it could be shown that, accompanying or subsequent to the development of such an illness the patient actually became immune to poliomyelitis, one might justifiably assume that he had passed through an attack of the disease. The elucidation of this problem must rest on further observations and experiments on the nature of immunity in this and other diseases, together with an appreciation as to whether the tests now at our disposal are an adequate measure of immunity to poliomyelitis.

## SUMMARY

1. An epidemiologic study of poliomyelitis has been made in which particular emphasis is laid on the problem of so-called abortive poliomyelitis, in an effort to define this entity, to determine its relative frequency, and to uncover methods whereby it can be recognized.

2. Common usage of the term abortive poliomyelitis has proved so ambiguous that in order to define the issues in this disease we have employed the term characteristic minor illness in association with poliomyelitis, so that ground may be cleared for a critical, definitive study.

3. The symptomatology of some of these minor illnesses is more or less characteristic but not specific, being essentially that of an acute infection of short duration. Such symptoms as fever, sore throat, headache and vomiting dominate the clinical picture.

4. In a survey of 222 families in each of which one or more cases of poliomyelitis had occurred it was found that, coincidentally with the onset of the known case or cases of poliomyelitis, characteristic minor illnesses developed with a high degree of frequency in the other children of susceptible age. Thus in the age group 1 to 4 years, 39 per cent of children with familial exposure developed a minor illness and in the age group of 5 to 9, this incidence was 32 per cent. In sixty control families comparable data were obtained, showing that while the epidemic prevailed, the incidence of similar minor illnesses was about 9 per cent among local children under 10, who had not been exposed to a familial case of poliomyelitis.

5. In a survey of three communities the ratio of cases of poliomyelitis to these characteristic minor illnesses was the same in each; namely, 1 : 6.

6. Experiments were made in which the poliomyelitic virus was isolated from nasopharyngeal washings in two examples of these minor illnesses. Negative results were obtained in ten others.

7. In both the successful experiments of virus isolation, the nasopharyngeal washings were obtained on either the first or the second day of the disease; three other attempts to isolate the virus during this period proved negative.

8. Strong evidence is brought to bear that these minor illnesses, which are evidently more frequent than has hitherto been suspected, have a common causal *relationship with orthodox poliomyelitis.*

9. The question as to whether the term abortive poliomyelitis may be justifiably ascribed to these illnesses would seem to be one of definition.

# THE TOXICITY OF ALLYL ALCOHOL

CAREY P. McCORD, M.D.
CINCINNATI

Allyl alcohol, $C_3H_5OH$, earlier came into prominence as a toxic substance through the belief that its presence in wood alcohol (methyl alcohol) as an impurity largely accounted for the toxicity of the latter substance. Allyl alcohol may be present in natural methyl alcohol in such quantities as 0.5 per cent. This attempt to shift the major responsibility for wood alcohol poisoning to its impurities proved to be unwarranted. It is now known that pure synthetic methyl alcohol possesses toxic properties essentially equal to those of the natural variety.

Genuine opportunities for injury from allyl alcohol may be found in the increasing use of this substance as an intermediate in the chemical and pharmaceutic industries. During the past year a number of workers have been damaged from exposure to allyl alcohol vapors, which fact prompted a limited experimental investigation, here reported. Earlier investigations have been reported by Miessner,[1] Carlier[2] and Atkinson.[3] The last mentioned investigator found that 0.5 cc. of allyl alcohol in 1 per cent solution, administered by mouth, produced death in dogs within about seven hours. Atkinson concludes that the toxicity based on the lethal dose is about 150 times that of methyl alcohol.

## INHALATION EXPERIMENTS

Six rabbits, one monkey and sixteen white rats were subjected to the action of known concentrations of allyl alcohol, in such quantities of the vapors as 50, 200 and 1,000 parts per million of air. The exposure period was seven hours daily, although some animals did not survive that long. The method of exposing these subjects to the vapor is described in other publications.[4]

Following exposure to 1,000 parts of vapor per million of air, the one rhesus monkey, long under preliminary observation, died within four hours. Prior to death there occurred profound vomiting and diarrhea, together with every indication of severe pain. At autopsy, subcutaneous hemorrhage was noted over the abdomen; the entire intestinal tract was markedly inflamed and injected, with petechial hemorrhage throughout. The gastro-intestinal tract was empty and greatly distended. The entire spleen presented diffuse hemorrhage. Similarly, hemorrhage existed in the kidneys, and throughout the lungs extensive edema with hemorrhagic exudate was noted. Additional evidence of inflammation, with or without hemorrhage, was noted in the brain, meninges and blood vessels. The blood was uncoagulated.

Two rabbits were subjected to the same concentration. One died after three and a half hours' exposure, the other after four hours and fifteen minutes. During exposure, breathing was labored and noisy. Fluid dripped from the nose and mouth. At autopsy much free hemorrhage was found in the lungs, with lesser inflammation and hemorrhage in the intestinal tract, kidneys and bladder. The urine contained blood. In one of these two rabbits, hemorrhage was noted in the eyes, the sclerae were opaque, and the genitalia were highly inflamed. Both animals presented a marked gaseous distention of the gastro-intestinal tract.

Six rats were exposed to this concentration of 1,000 parts of vapor per million of air and were dead within three hours. The postmortem observations in the lot were the same throughout and closely resembled those found in the rabbits and in the monkey.

In another group of three rabbits and four rats, the concentration was reduced to 200 parts of allyl alcohol vapors per million of air. After one hour's exposure there existed obvious discomfort and labored, noisy breathing, with discharge of fluid from the nose and mouth. One animal survived three days' exposure (seven hours each), dying in convulsions; another survived six days' exposure, and the third survived eighteen days' exposure. During this period the labored, noisy breathing persisted, together with marked nasal and oral discharge of secretion. The autopsies on these three rabbits disclosed conditions quite similar to those found in the higher concentration, with some variations attributable to the longer period of action.

The four rats in this group succumbed on either the first or second day of exposure and presented conditions at autopsy similar to those already described.

In a third group of two rabbits and five rats, the concentration produced was 50 parts of allyl alcohol per million of air. The first rabbit died on the fourteenth day of exposure; the second survived twenty-eight days' exposure and was then killed for examination. In the first animal the conditions found at autopsy were similar to those already mentioned. In the killed animal the changes were likewise similar, with chief evidence of hemorrhage in the gastro-intestinal tract and the lungs.

The rats in this series, with one exception, died as the result of the action of allyl alcohol, the exposure period averaging about thirty days.

In general, it appears that allyl alcohol is a highly irritating chemical, leading in life to pulmonary edema, hemorrhage, gastro-enteritis, profound vomiting, distention of the gastro-intestinal tract, diarrhea, nephritis and hematoma. At autopsy, practically all tissues are highly inflamed and present hemorrhage. The lungs and gastro-intestinal tract appear to be the most involved.

A suitable number of controls did not present any of the abnormalities observed before death and at autopsy in the animals exposed to the vapor.

Tissues from these experimental studies have been examined by Dr. Ernest Scott and his associates, of the Department of Pathology of Ohio State University. Histologic changes will be reported in a separate paper. The summary of this paper on pathology includes the following: "All lesions described have been of a very acute nature. The alcohol is apparently diffused quite rapidly throughout the system. The first evidence of the injurious agent is a general congestion of all the viscera. This is followed quickly by swelling and granular degeneration of the cytoplasm of the parenchymatous cells. The cells most affected are those lining the convoluted tubules of the kidney, the liver cord cells, myocardium, and the ganglion cells of the spinal cord and of the retina. This swelling and parenchymatous change is followed directly by cellular necrosis without any evidence of wandering cell infiltration. . . . The general congestion of the lungs is followed by edema and compensatory emphysema."

Chem. **23**: 931 (Aug.) 1931.

### COMMENT AND SUMMARY

Among workers the damage from allyl alcohol has been limited to severe irritation of the mucous membranes, with edema and excessive secretion, together with conjunctivitis and lacrimation. The physical properties of this alcohol are such as to provide due warning of its presence. Since, under ordinary room conditions of temperature and air pressure, 1 cc. of the liquid allyl alcohol will produce about 362 cc. of vapors, it is obvious that dangerous concentrations may readily arise. The threshold of danger from inhalation is well below 50 parts of vapor per million of air, but it is improbable that allyl alcohol may be regarded as 150 times as toxic as methyl alcohol through this portal of entry. Concentrations below 5 parts per million will produce some irritation, and for practical purposes the atmosphere of work places should be kept below this point. Completely closed systems are highly desirable in the manipulation of this toxic industrial chemical.

34 West Seventh Street.

# PROPHYLAXIS OF THE ANEMIA OF PREMATURE INFANTS

## USE OF VARIOUS AGENTS IN ATTEMPT TO PREVENT DEVELOPMENT OF THE SO-CALLED PHYSIOLOGIC ANEMIA OF PREMATURE INFANTS: PRELIMINARY STUDY

ARTHUR F. ABT, M.D.
AND
BETH REYNOLDS NAGEL, S.B.
CHICAGO

The anemia that regularly occurs in premature infants during the first quarter year of life has been known and recognized as a clinical entity since Gundobin [1] first reported his observations on this condition.

For the first days after birth the blood of the premature infant shows high values for hemoglobin content and number of erythrocytes, similar to the values found in the full term new-born infants. At this period fetal characteristics such as erythroblastosis and polychromia are present to a higher degree in the blood of the premature than of the full term infant.

Regularly during the first three months there is noted a marked drop in the hemoglobin and the red count, beginning from the fourth to the fifth week of life and reaching their lowest values between the eighth and the twelfth week. Thereafter, a gradual improvement in both the erythrocyte count and the hemoglobin content of the blood are noted, until values are reached at the sixth to the eighth month of life which compare normally with those of the full term infant.

The more premature the infant and the lower its birth weight, the more severe the anemia that is likely to develop.[2]

It must be clearly understood that all workers on this anemia have reported their observations from otherwise healthy premature infants, so that such factors as infection, hemorrhage or ailmentary or nutritional disturbances are *a priori* excluded. The anemias of congenital syphilis, or those developing after severe infections or nutritional disturbances in the new-born or premature infant in the first six months of life, have their definite etiology and must be recognized as entirely distinct types from those occurring in otherwise healthy premature infants.

While many of the earlier observations were made on infants from the lower social strata, in infant asylums and crèches, there have been enough observations on premature infants of the upper classes to prove that the anemia develops just as severely and regularly in infants from the latter social group.

It was early believed that the type of milk or feeding might have some influence on the development of the anemia, but whether the feeding is entirely breast milk or modifications of cow's milk makes not the slightest difference in the degree of anemia developed. The early addition of vitamins, orange juice, cod liver oil or viosterol does not prevent the development of the anemia.

### SYMPTOMATOLOGY

This anemia has been termed physiologic anemia [3] and also hypoplastic anemia [4] of premature infants.

The symptomatology of this anemia is often marked by intense pallor; the skin has a waxy or white sheet color. The ear lobes are pale and transparent and the mucous membranes and nailbeds are markedly pale. Enlargement of the spleen is uncommon; the liver is occasionally found slightly enlarged. Kunckel [5] reported that premature infants whom he was able to keep out in the fresh air showed a rosy skin color despite the anemia which they developed. The appetite and general well being of these infants is in no way impaired, and they show no elevations of temperature or constitutional derangements. No immunologic studies are available to show that this anemia renders them more subject to infection.

The blood of this anemia is characterized by an equally marked reduction in erythrocyte and hemoglobin values with disappearance of the erythroblastosis and polychromia. The latter finding is in marked contrast to the prevalence of these elements in the blood of premature infants during the first few days of life.

### EXPERIMENTAL DATA

The experimental work here reported was carried on in a special ward for premature infants, under ideal and exemplary conditions. After the infants were discharged from the hospital they were followed in the outpatient department, returning at intervals to a special premature clinic.

All infants selected were healthy premature infants; i. e., there was no history or sign of syphilis, hemorrhage, infection or other disorder that might be taken as a cause for anemia. In our work we have divided them into two distinct classes: those born after six to seven months' gestation and those born after eight months' gestation. This was necessary because it has

been shown that the more premature the infant and the less the birth weight, the more severe the anemia. This group differentiation was likewise made with the control series.

The infants in this station[6] are all placed in the Hess incubator bed for premature infants, and heat is maintained by this means. The routine feeding is breast milk obtained from tested wetnurses who live in the hospital and express their milk under direct control of the supervising nurse of the premature station.

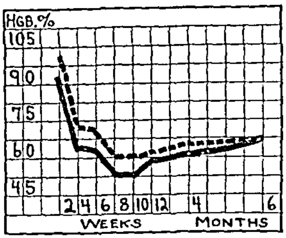

Chart 1.—Hemoglobin in control premature infants. In charts 1 and 2 the broken line indicates the infants of eight months' gestation and the solid line those of from six to seven months' gestation.

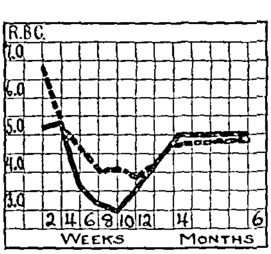

Chart 2.—Red blood cells in control premature infants.

After the infants are older and have attained sufficient weight, such substitute feedings as skimmed lactic acid milk (buttermilk), whole buttermilk, chymogen milk, evaporated milk and whole milk modifications are adopted, according to the need of the infants. Orange juice and cod liver oil are started early, from the second to the third week after birth; cereals from the fourth to the fifth month, and vegetables from the fifth to the sixth month. The infants were followed for from six to seven month periods, after which time the erythrocyte and hemoglobin values had returned to normal figures for this age group.

*Prophylactic Agents Used and Dosages.*—The first group of premature infants was started on a dried liver extract fraction suitable for secondary anemia, made according to the formula of Whipple and Robscheit-Robbins.[7] Two complete blood determinations were made during the first week of life, and then the dried liver extract was administered at the beginning of the second week of life and kept up continuously, with daily dosages throughout the experiment. The initial dosage of liver extract was 0.5 Gm. twice daily, increased with age to 1 Gm. twice daily and up to 3 Gm. twice daily as the infant gained and grew older.

In another series a preparation of desiccated hog stomach, prepared under the direction of Isaacs and Sturgis[8] and purchased on the open market, was employed in similar dosages and started after the first week of life.

In the largest series a preparation of dried liver fraction with iron was employed. The liver in this preparation was in the form of the dried liver fraction suitable for secondary anemia, made according to the formula of Whipple and Robscheit-Robbins.[7] The iron in this preparation was in the form of ferrous ammonium citrate. Each level teaspoonful of this empiric formula contains approximately 3.75 Gm. of liver fraction and 0.65 Gm. (10 grains) of ferrous ammonium citrate. The initial dosages started with from 1 to 2 Gm. twice daily and were increased up to 4 Gm. twice daily as the infants grew older. This preparation, which was started after the first week of life, was easily and well tolerated in these doses and caused no disturbance in the infants' digestion, feedings or stools. The amount fed twice daily was mixed with 1 drachm (4 cc.) of the milk mixture and was given at the end of a feeding. As the infants' grew older the liver-iron preparation was given in from one-half to one ounce of milk formula.

The control group of infants was in the same ward under identical conditions of nursing, maintenance of heat, diet and hygienic care. Whenever possible, premature twins were used, one as a control and one as an experimental subject.

### HEMATOLOGIC METHODS

Erythrocyte and leukocyte counts, hemoglobin determinations, platelet counts, reticulocyte percentages and differential counts were taken on the premature infants at weekly intervals while they were in the hospital and at biweekly intervals after the infants were discharged. United States standard pipets and a Thoma Levy hemocytometer were used for all erythrocyte and leukocyte counts. Physiologic solution of sodium chloride was used to dilute the erythrocytes and 3 per cent solution of acetic acid for the leukocytes. William's improved Newcomer hemoglobinometer was used for hemoglobin determinations, and platelet counts were made by the direct method. The estimation of the reticulocyte percentages were made from counts of 1,000 erythrocytes on blood films, vitally stained with brilliant cresyl blue and counterstained with Wright's stain. Differential counts were made on cover glass, evenly spread blood films stained with May-Greenwold Giesma stain. The blood was obtained by pricking the heel, finger or ear lobe of the infant, so that a free flow was obtained.

The complete protocol record for each infant may be seen in table 5. The effect of prematurity on the red cell count and hemoglobin content is illustrated in table 1 and in charts 1 and 2 for the control series. The shorter the intra-uterine life or the more premature the infant, the more severe was the anemia that developed.

The red blood cells were of normal shape and size at birth, and in those infants who developed anemia with erythrocyte and hemoglobin values under 3 million and 45 per cent, respectively, anisocytosis and poikilocytosis were noted. These changes were most marked, the more severe the anemia.

Nucleated red blood cells and polychromia of the erythrocytes were present and both were in normal numbers for premature infants. This is more pronounced in the premature than in the full term infant.

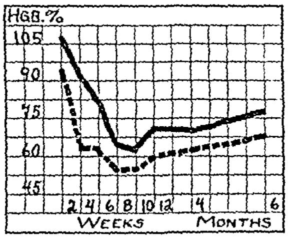

Chart 3.—Hemoglobin in premature infants of from six to seven months' gestation given liver fraction and iron. In charts 3, 4, 5 and 6 the solid line indicates infants given liver fraction and iron and the broken line indicates the control.

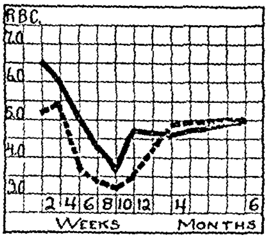

Chart 4.—Red blood cells in premature infants of from six to seven months' gestation given liver fraction and iron.

By the fourth week of life these elements have disappeared, and they do not again reappear during the course of the anemia.

The reticulated red blood cells are highest in number at birth and in the first few weeks of life and thereafter retain a more or less constant level, regardless of the administration of liver fraction, desiccated hog stomach or liver fraction and iron in combination. We were unable to confirm the observations of Frank,[9] who found an increase in reticulocytes with the administration of ferrum reductum. Yang and Keefer[10] have recently reported on the response of reticulocytes in secondary anemia following administration of liver and of liver and iron to adults suffering with malaria, hookworm anemia, and other conditions. Evidently physiologic anemia of prematurity does not show the reticulocyte response that the administration of these substances can produce in certain anemias of the adult.

The hematologic studies of the white blood corpuscles in the premature infants here investigated showed no deviation from the normal age-for-age values noted in the comprehensive studies of other observers.[11]

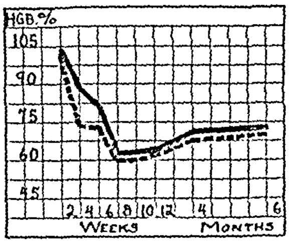

Chart 5.—Hemoglobin in premature infants of eight months' gestation given liver fraction and iron.

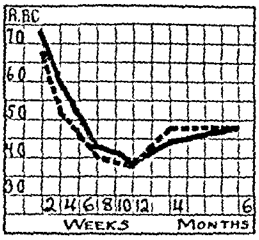

Chart 6.—Red blood cells in premature infants of eight months' gestation given liver fraction and iron.

Unlike the disappearance of normoblasts and polychromia in the red cells, there is no sign of hematopoietic insufficiency in the leukocytic cells.

### RESULTS

The prophylactic value of liver fraction alone and desiccated hog stomach alone in the small series of cases in which they were tried gave average results which compare so closely with our control figures that we cannot claim beneficial results for them. Their early and continuous administration did not seem to prevent the development of physiologic anemia of the premature infant (tables 2 and 3). The premature infants of from six to seven months' gestation in these series developed as severe an anemia as our control groups, and those of eight months' gestation, who were larger premature infants, also averaged as comparatively severe anemias as were found in the control series.

The results of the administration of liver fraction and iron in combination, in the series here reported, show a definitely less severe anemia when the averages are compared with control groups for premature infants of from six to seven months' and eight months' gestation (table 4, charts 3, 4, 5 and 6).

The most beneficial results seem to have been obtained in the six to seven month groups, in which there can be no doubt that high averages have been maintained for both red blood cells and hemoglobin values.

### COMMENT

The use of various therapeutic agents in attempts to cure the anemia of prematurity has led to considerable controversy in the reports of various observers. Few, if any, adequate prophylactic attempts have been made to prevent the development of this anemia. This is easily understood when it is realized that such a procedure must be commenced very shortly after birth, as the anemia is so rapid in development. These infants must be started with prophylactic medication within the first ten days to two weeks after birth if the anemia which becomes evident at the sixth to the eighth week is to be prevented.

*Iron Therapy.*—There is a disagreement among various observers on the prophylactic and therapeutic use of iron and its effect on this anemia.[12] Lichtenstein[4] (1917) stated that iron therapy in large doses has a curative effect on the anemias of premature infants. The same author[4] (1921) concludes that his prophylactic attempts at prevention of premature anemia with iron medication were unsuccessful. Lotte Landé[2] (1919) did not consider and disapproved of alimentary medication, using intramuscular blood therapeutically. In a second article[2] (1926) she states that by feeding large doses of ferrum reductum, from 1 to 2.5 Gm. daily, she was able to prevent, to some extent, the development of as severe an anemia as usually occurs. Her conclusions are drawn from a series of eight cases.

*Iron.*—Besides the lack of clinical agreement on the therapeutic effect of iron in premature anemia, there is a general lack of agreement on the benefits of the oral administration of iron in any type of secondary anemia.[13]

It has been shown experimentally, in anemia due to hemorrhage in dogs, that above a certain optimal intake level a large excess of iron gives no further rise in the production of hemoglobin. In these experiments the type of iron salt given seemed to make no difference, whether it was fed as ferrous chloride, ferric citrate, ferrous carbonate, ferrous ammonium sulphate or other iron salts.

The exact mechanism of the action of iron in blood regeneration in secondary anemias is still unknown. It may simply supply the needed lack of iron; it may

[12] Baar, Heinrich; and Stransky, Eugen: Die klinische Hamatologie des Kindesalters, Leipzig, Franz Deuticke, 1928, pp. 46-49.

[13] Iron in Anemia, editorial, Intern. M. Digest **18**: 252 (April) 1931.

stimulate hematopoietic function either directly or by indirect stimulation of internal body metabolism; or it may act as a catalyzing or oxidizing agent, either in the blood itself or on hematopoietic organs.

Frank[9] stated that, by the administration of ferrum reductum, he was able to some extent to prevent the development of physiologic anemia of premature infants, and also, by vital staining, he demonstrated considerable increase in reticulated erythrocytes. The latter observation has not been substantiated by other observers and was not noted in the series of cases here reported.

Other observers have been unable to substantiate the results of Lotte Landé and Frank[9] and have found that the prophylactic feeding of iron starting in the first few weeks of life will not prevent or alter the development of physiologic anemia.[14]

Langstein and Edelstein[15] and others measured the iron metabolic balance for full term infants and found a small positive surplus. Lichtenstein,[4] on the contrary, found a small negative iron balance for premature infants. The exact iron resorption is difficult to measure, and so far remains undetermined, and may be a factor in the etiology of the anemia. Lichtenstein concludes that of large doses of administered iron only a very minute quantity is resorbed and retained, though the possibility exists of changing the negative to a positive balance by feeding massive doses of iron.

* *These infants were white twins of eight months' gestation. The control twin was slightly heavier and larger.*

*Effect of Heliotherapy on Anemia.*—It has been mentioned that Kunckel[5] showed that those infants whom he was able to keep outdoors developed anemia although they had a more rosy color than those kept indoors. Pfaundler[16] and others have believed that restriction and lack of sunlight might be a causatvie factor in the development of anemia. Sanford[17] in working on the effects of irradiation of new-born infants with ultraviolet rays was able to show a transient rise in erythrocyte and hemoglobin values.

In reviewing the literature, Hoeffel and Lyons[18] conclude that there is no justification for the belief that light rays, including ultraviolet rays, have any lasting specific effect on the hemoglobin and erythrocyte values of the blood. They have pointed out a slight seasonal variation in the values, but Landé[2] (1919) and others have shown that the anemia develops with equal severity in premature infants at all seasons of the year.

Furthermore, it has been shown by numerous authors[19] that cod liver oil and irradiated ergosterol have no effect on prevention of anemia in full term infants. Wundt's[20] claims for the proprietary preparation Ferronovin (which contains dried fish liver, iron and irradiated ergosterol) as having a preventive value in prophylaxis and therapeutic effect of physiologic anemia have been conclusively refuted by Ulmer.[21] Similarly the use of small doses of egg yolk,[22] even though added to the diet early, has never been successful in preventing the development of this anemia.

*Liver and Iron.*—The recent work of Whipple and Robscheit-Robbins[23] has demonstrated that a liver fraction which contains from 65 to 70 per cent of the potency of whole liver and probably a number of active substances, and which represents only 3 per cent of the weight of whole liver, is an effective therapeutic agent

[illegible] S.: The Regeneration of Hemoglobin and [illegible] 9: 688 (Oct.) 1929. Whipple, Robscheit- [illegible] in cases of secondary anemia. Furthermore, they were able to demonstrate experimentally in dogs that it was obvious that the effect from oral administration of iron was more than a mere replacement in the lost or worn out hemoglobin molecule. They further state that "iron in excess of hemoglobin iron requirements obviously exerts some influence upon internal body metabolism," by producing more hemoglobin. This phenomenon they have termed a "salt effect," and it may occur similarly in the feeding of salt mixtures of copper and other metals and ash from liver and kidney.

Finally it has been found that by feeding liver and iron in combination a "summation effect"[24] was produced, the resulting increase in production of hemoglobin and red cells being the total effect of the organ feeding plus the original value due to iron administration alone.

Keefer and Yang[25] have reported that iron and liver given in combination to patients suffering with secondary anemia, especially in anemia due to hookworm infestation, showed improvement more effectively than when either liver or iron was given alone.

Hugh Josephs[26] has recently reported on the effect of feeding a number of premature infants iron alone, iron and copper and iron and liver in combination. He concludes that liver and iron in combination have apparently the most successful effect when used therapeutically after the physiologic premature anemia has developed.

*Iron and Copper.*—In the most recent literature there have been some experimental and clinical reports[27] on the use of iron in combination with copper employed therapeutically in secondary anemia. However, these results might be considered as the "salt effect" previously described. We have assumed that the "summation effect" of the liver-iron combination, plus the unknown influence of iron on internal metabolism, would be, theoretically at least, the most suitable for the prevention of physiologic premature anemia. Schiff and Joffe,[28] in a recent report of twelve cases, have demonstrated the failure of copper and copper and iron in combination to give prophylactic or therapeutic results in premature anemia.

In these experiments, therefore, we have not attempted the prophylactic use of the iron-copper combination, though it may still be tried out in a continuation of this work.

## SUMMARY

In the prophylaxis of premature anemia it may be concluded that iron therapy alone is of doubtful value. Further, neither the use of desiccated hog's stomach (ventriculin) nor the use of liver fraction alone proved of value in the prevention of the anemia.

Favorable results seem to have been obtained in the prophylaxis of the anemia of premature infants through the use of a dried liver fraction combined with ferrous ammonium citrate.

The most marked results in this series of experiments were obtained in the group of premature infants, of from six to seven months' gestation, in which the development of the anemia was most severe. No definite conclusions as to the etiologic factors causing this anemia may be formulated from the experimental data which we obtained. In reviewing the literature, the following theories[29] for the cause of anemia of premature infants are most tenable: (*a*) the lack of an adequate iron reserve depot, and its early depletion; (*b*) a functional insufficiency of an imperfectly developed hematopoietic system.

The chief objection to the depleted iron reserve depot for explaining physiologic anemia of prematurity has been the fact that the prophylactic feeding of iron has not prevented the development of the anemia. Possibly the iron even though administered in large doses has been resorbed and retained only in minute quantities.

The functional incapacity of the hematopoietic system may be analogous to the incomplete and imperfect development of the gastro-intestinal, cardiovascular and heat regulating systems of the premature infant. At the sixth to the eighth month of intra-uterine life, the hematopoietic system is probably still somewhat imperfectly developed, and, therefore, functionally incapable of adequately responding to the additional demands of extra-uterine life.

This theory would help to explain the lower erythrocyte and hemoglobin values found in the premature infants of from six to seven months' gestation as compared to the premature infants of eight months' gestation. The exact mechanism of the development of this anemia still remains unexplained.

This is a preliminary report of an experimental attempt to prevent the development of the physiologic anemia of premature infants. The data obtained indicate that a combination of liver fraction and ferrous ammonium citrate, started within the first fourteen days after birth with initial dosages of from 1 to 2 Gm. twice daily, and increased up to 4 Gm. twice daily, was the most efficient of the prophylactic agents investigated. There was a definite response to this prophylactic agent, which was most marked in the series of premature infants of from six to seven months' gestation, in which group the anemia is most severely developed.

It is hoped that a continuation of this investigation with other mineral combinations or organic and mineral material in various percentages and dosages may yield further data on the prophylaxis of the anemia of prematurity.

[29] In a recent article, G. Sanpaolesi (Jahrb. f. Kinderh. **132**:277 [Aug.] 1931) advances theoretical and experimental evidence in support of the theory that an increase in the fluid volume of the blood causes this premature anemia through dilution. According to the author, this hydremia mechanically lowers the erythrocyte count and the hemoglobin value.

**Myasthenia Gravis.**—Myasthenia gravis was first described by Wilkes in 1877. Since then about 300 cases have been reported and several excellent reviews have appeared. . . . The condition can probably be most briefly defined as a symptom complex characterized by sudden, intermittent and progressive clinical weakness of a muscle or muscle group, often terminating in death and leaving almost no pathologic changes despite the marked symptoms during life. No race is immune to this condition. According to Campbell and Bramwell, no case is on record in which more than one member of a family has been affected. Noyes, however, reported a sister and father of one patient to be similarly afflicted.—Abraham, S. V.: *Arch. Ophth.* **7**:700 (May) 1932.

# THE SYMPTOMATOLOGY, DIAGNOSIS AND TREATMENT OF STRONGYLOIDES INFECTION

ERNEST CARROLL FAUST, Ph.D.
Professor of Parasitology, Department of Tropical Medicine, Tulane University of Louisiana School of Medicine
NEW ORLEANS

The relatively frequent occurrence of Strongyloides infection throughout the southern part of the United States and the appearance of patients harboring this infection in clinics in the North call for more careful attention than has been given to this disease in the past. The larvae of the etiologic agent, Strongyloides stercoralis, were discovered in 1876 by Normand[1] in the stools of French soldiers who had contracted an uncontrollable diarrhea in Cochin China. At necropsy of five of these patients who succumbed to the diarrhea, delicate parasitic nematodes were recovered from the wall of the ileum and from the biliary and pancreatic ducts. Cases were soon diagnosed and studied by Grassi[2] and by Perroncito[3] in Italy. Leuckart[4] demonstrated that the parasitic and stercoral types in this infection belonged to alternate phases in the life cycle of the same organism, while Durme,[5] Ransom[6] and Fülleborn[7] proved that the filariform larvae of the worm invades man by the same route (i. e., by the skin) and migrates through the same organs and channels as the hookworm.

## BIOLOGIC BACKGROUND

The female parasitic worms live in the mucosa of the small intestine, especially the duodenum and upper jejunum. In heavy infections the pyloric stomach wall, the common duct, the proximal biliary and pancreatic passages, the ileum, and even the cecum and colon may be involved. Aberrantly, adult worms and larvae may be recovered from practically all the organs and cavities of the body. Usually the eggs of the worm are laid in the intestinal mucosa, work their way out into the lumen, and are carried down the intestine, meanwhile maturing, so that they ordinarily hatch before being passed in the feces. Since the days of Leuckart, two types of development have been known, the direct and the indirect mode. In the former type, the hatched larvae (rhabditiform stage) are passed in the feces, feed ravenously on the excrement and metamorphose into filariform larvae, which, after casting their sheaths, are infective by way of the skin or the mucous membranes. Under favorable conditions of moisture and temperature the infective stage is able to survive for many weeks outside the body, although these larvae are much more sensitive to unfavorable conditions than is the similar stage of the hookworm. In the indirect type, which is much more common in the tropics than in cooler zones, the rhabditiform larvae, which are passed in the feces, feed and become transformed into "free-living" males and females, which mate and give rise to a daughter progeny of rhabditiform larvae. The latter feed and are changed into filariform larvae, which then and only then are infective for man. In the indirect type the development of the complete extrahuman phase of the life cycle takes place very rapidly (from two to five days) and the infective filariform larvae seldom live beyond the twelfth day following evacuation of the first-stage rhabditiform larvae in the stool.

While I was working in Panama during the summer of 1930, I[8] studied several cases of Strongyloides infection with symptoms of uncontrollable diarrhea and severe dehydration. The stools of these patients were teeming with dwarf filariform larvae. A study of the larvae showed that they had metamorphosed without feeding and that they developed no further. For a period of nine to twelve days they were infective through the skin and mucous membranes; otherwise they perished. Further investigation revealed the fact that in passing out of the intestine the infective filariform stage came in contact with the rectal mucosa and was able to penetrate through this membrane into the tissues, later passing through the blood stream into the lungs and out through the air passages into the pharynx and down into the intestine. This discovery explains the pathologic study of Ophüls[9] on a human necropsy and certain experimental observations of Fülleborn[10] and Nishigori.[11] This shortened mode of development to the infective stage I have designated the hyperinfective type.

## PATHOLOGIC AND CLINICAL OBSERVATIONS

At the site of invasion through the skin there may develop in twenty-four hours a profound erythema, which becomes progressively more intense up to the fourth day, when lupous patches are observed. This is comparable to the "ground itch" of hookworm infection. From twenty-four to forty-eight hours after exposure to the infection, an acute local inflammatory reaction may take place in the lungs as the result of the migration of the larvae from the capillaries into the bronchioles. This condition has not been reported for hookworm infestation but parallels the bronchial pneumonitis observed in ascariasis when Ascaris larvae are migrating through the lungs. Later on, when the larvae have worked their way into the intestinal mucosa (frequently into Lieberkühn's glands) and have developed into the delicate coiled adult worms, they feed on the tissues and lay their eggs, which break through into the intestinal lumen. They provoke a catarrhal inflammation of the invaded mucosa, with round cell and eosinophil infiltration. The degree of these lesions is dependent on the number of embedded worms and the length of their activity. In severe cases there is extensive erosion of considerable areas of the pyloric, duodenal, jejunal and ileac mucosa, so that it has a raw beefsteak appearance. Where the large bowel is also involved, similar lesions occur. Usually there is no marked generalized eosinophilia but occasionally this is pronounced.

[11] Nishigori, M.: The Facto [illegible] the External Development of Strongyloides Stercoralis and on Autoinfection with This Parasite, Taiwan Igakkai Zasshi, 1928, number 276, pp. 1-56 (Japanese text with English abstract).

In very light infections with Strongyloides there are frequently no demonstrable symptoms; in moderately heavy infections or those of long duration there is commonly a diarrhea following epigastric distress after meals, alternating at times with constipation; in severe infections (usually of the hyperinfective type) there is an intractable diarrhea, with macroscopic or occult blood, and undigested food. The faulty digestion and severe drain of liquids from the system produce emaciation of the most advanced type. Occasionally there is sufficient toxic absorption to induce profound toxic edema. Fortunately for physicians practicing in the United States, the latter type is not commonly observed except in cases from the tropics.

Diagnosis is based on finding the typical motile rhabditiform larvae in the stools. These can be most readily obtained by centrifugating a small sample of the stool previously comminuted in water and strained through cheese cloth. Strongyloides larvae require differentiation from the similar stage of the hookworm, which have a much longer pre-esophageal (premuscular) mouth cavity. Furthermore, in freshly passed stools the hookworm embryos are almost always within the unhatched eggs. In cases of severe diarrhea, unhatched eggs of Strongyloides occasionally are found. These should be left in the stools until they hatch, in order to obtain a satisfactory diagnosis, since the egg is very similar to that of the hookworm.

In the hyperinfective type the filariform larvae may be identified by their diminutive size and the minute terminal notch in their tail. Occasionally parasitic females and males are passed in diarrheic stools. The former are delicate threads just visible to the naked eye and contain eggs in a bicornate uterus. The rare parasitic males are practically indistinguishable from the "free-living" males of the indirect cycle.

### THERAPEUSIS

Until 1928 there was no specific treatment for strongyloidosis. In that year DeLangen[12] in Java indicated the efficacy of gentian violet in reducing the toxic effect of the parasite in severe cases and in some instances causing eradication of the worms. In 1929 I[13] used this agent for the first time in the United States. At least 200 cases (about 6 per cent infection in the New Orleans Charity and Welfare clinics) have on my recommendation been treated by New Orleans physicians with gentian violet. Of this number I have made follow-up examinations of forty-seven patients and all but two have been freed of the infection. In most cases a single course of treatment was sufficient to eradicate the worms. This consisted of two one-half grain (0.03 Gm.) enteric coated tablets of the dye (National Aniline and Chemical Company product) administered by mouth three times a day before meals for a period of from seven to ten days. In four cases, two courses of treatment were needed. There is no contraindication to administering the drug but patients have been cautioned to report if the urine was ever violet colored. Up till now no such report has been received. Two patients reported mild nausea, but there was no similar complaint from the others. The dye operates by staining the mucosa of the intestine a brilliant violet (undoubtedly a vital cytoplasmic reaction). The adult parasitic worms living in the mucosa absorb the dye and are very susceptible to its toxic effect, become free from the mucosa, and may be passed in the feces. Any portion of the dye that is absorbed beyond the intestinal mucosa is soon reduced to a colorless substance. Strangely enough the eggs and young larvae are not readily killed. Furthermore, small amounts of the dye modify the indirect and hyperinfective type into the direct type, thus minimizing the danger of the infection before the parasites are actually killed.

### CONCLUSIONS

Physicians in the South are more or less familiar with Strongyloides infection. Owing to previous inability to eradicate the worms, the patients treated have returned time after time or have gone to other physicians for help. It is recognized that Strongyloides infection is not always the cause of intestinal symptoms which have been referred to it, but in many cases eradication greatly improves the condition and at least allows the physician to eliminate the organisms as a possible causative factor in the symptomatic complex. In severe infections the clinical picture is so clear that, once the relationship is known, there is no difficulty in associating cause and effect. It is believed that the time is ripe for a more intensive study of Strongyloides infection on the part of both the internist and the laboratorian.

# TREATMENT OF AGRANULOCYTIC ANGINA WITH CALCIUM GLUCONATE

## REPORT OF CASE, WITH AUTOPSY

R. A. HARE, M.D.
AND
J. H. CHILDREY, M.D.
SANTA BARBARA, CALIF.

Cases of agranulocytic angina are of interest because of its unknown etiology, its high mortality rate and the lack of knowledge of any specific treatment. It is even doubted whether the condition is a syndrome or a distinct clinical entity. The following fatal case was interesting because the patient was an allergic individual, and because an improvement in the blood picture was noted following the administration of calcium gluconate:

### REPORT OF CASE

A woman, aged 44, married, was treated at the Santa Barbara Cottage Hospital between Sept. 7 and Oct. 10, 1931, for obesity and hypertension, both of which had been present for fourteen years. She also complained of symptoms referable to the menopause, of several months' duration.

During the preceding twelve years she had undergone a cesarean operation, cholecystectomy and appendectomy, and a pad of fat had been removed from the abdomen. For four years she had experienced allergic symptoms whenever she ate pineapple. Red and white blood examinations with differential counts were normal in August, 1917, and in February, 1930, the red and white blood counts were again normal. The family history was negative except that the patient's mother had diabetes.

Physical examination disclosed an enlarged heart, myocardial degeneration and marked obesity. Varicose veins were present on both lower extremities. Roentgenograms of the skull showed a thick, irregular, very dense calcified deposit on the inner aspect of the frontal bones and on each side of the sagittal

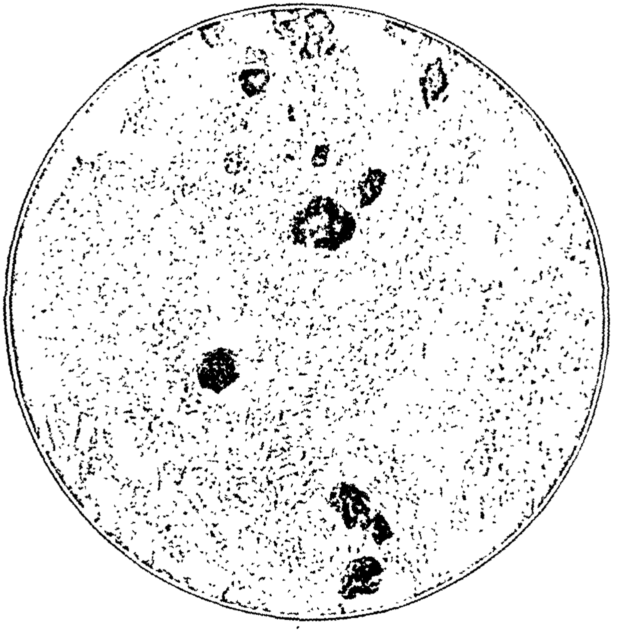
From the Sansum Clinic

suture. In the mouth, situated in the midline of the hard palate, was an exostosis measuring 1 by 1.5 by 2.5 cm. Several teeth were devitalized. The tonsils had been removed.

*Gastric analysis, red and white blood counts, and examination* of the stool revealed nothing noteworthy. The blood Wassermann reaction was negative. Traces of albumin and sugar were found in the urine; the excretion of phenolsulphonphthalein was 57 per cent in two hours.

The patient was hospitalized on an alkaline 800 calory reducing diet. During the ensuing month the blood pressure fluctuated between 152/100 and 224/136. By October 8 she had lost 10 pounds (4.5 Kg.), the headache was less severe, and the heart diameter had decreased 1 cm. by orthodiagram measurement. She was able to be up and her gait had improved.

October 10, she was discharged. Following an automobile drive that afternoon her throat became sore and the next morning when she planned to leave for her home the temperature was 101.4 F. She was kept in bed and treated for an infection of the upper respiratory tract. The next day the temperature was 103.6 and a blood count showed 1,200 leukocytes and only 43 cells on a smear, all of which were lymphocytes. The agranulocytosis persisted during the next eight days, as shown in the accompanying table. There was septic temperature, the highest point each day varying between 103.6 and 105.2. October 13 she complained of headache, soreness of the throat and neck, pain through all the teeth, soreness and stuffiness of the ears, and aching in the joints. The blood pressure had fallen to 140 systolic and 90 diastolic. On the posterior wall of the nasopharynx and in the hypopharynx at the left margin of the tongue were several small white ulcers, varying from 1 to 2 mm. in diameter. In the middle of the left tonsil fossa was another. The mucous membrane of the pharynx and of the gums on the right was moderately reddened. In the neck a few enlarged very tender lymph nodes were palpated.



Necrotic tissue from mouth, removed October 15, reduced from a photomicrograph with a magnification of 100 diameters There is marked vacuolization. An occasional round cell is visible. No polymorphonuclear leukocytes are present. A number of circumscribed oval or circular areas may be noted, up to 100 microns in diameter, consisting of finely granular blue material as if from deposits of calcium.

October 15 the throat, teeth and gums were very sore, but the generalized aching had subsided. The icteric index was 11. There was moderate edema of the mucous membrane of the pharynx and gums. The ulcers were twice as large, and several new ones had appeared on the gums and pillars of the palate.

October 16, the patient complained of soreness about the urinary meatus, but vaginal and rectal examinations were negative. There was a sensitive area in the upper right chest over the third rib. In the mouth there was considerable membrane formation over all the gingival surfaces. This was white, was of a soft though tough consistency, and was raised above the surface level of the surrounding mucosa. It peeled off readily, leaving a nonbleeding surface with very little evidence of inflammatory reaction. There was moderate edema of the arytenoids, and the white membrane of the left pillar of the palate had begun to peel off. The cervical lymph nodes were smaller and less tender. The skin had a dull icteric tint; the breath was fetid, and in the mouth the necrotic areas and superficial sloughing were more extensive, involving almost all the gum surfaces, the whole left posterior pillar of the palate and an area on the mucous membrane of the right hard palate which measured 1.5 by 2 cm. Treatment with calcium gluconate was started October 16, 1 Gm. in 10 cc. of solution being given intravenously each day for four doses.

*Differential Count*

| | Oct. 12-19, Inclusive | Oct. 20 | Oct. 21 |
|---|---|---|---|
| Leukocytes, per cubic millimeter | 736-1,300 | 1,700 | 7,500 |
| | | Percentage | |
| Lymphocytes (small) | 100 | 73 | 41 |
| Lymphocytes (large) | ... | 18 | 1 |
| Lymphoblasts | ... | .. | 4 |
| Monocytes | ... | 3 | 2 |
| Monocytes (large) | ... | 2 | 0 |
| Megakaryocytes | ... | 2 | 0 |
| Neutrophilic myelocytes | ... | 0 | 45 |
| Polymorphonuclear neutrophils | ... | 2 | 7 |

October 19, a mild degree of stupor was noticeable. The respiratory rate was 40 per minute. Numerous râles were audible over the lower right chest, but there was no evidence of consolidation. October 20, five days after treatment with calcium gluconate had been started, the first improvement in the blood picture was noted and the temperature was lower (102). The change in the condition of the blood suggested that, if death could be postponed a few days more, recovery might take place. On the following day the blood picture had improved still more, but the patient was moribund. The pulse was thready and the rate was 108 per minute. Blood pressure was 110 systolic and 86 diastolic. Examination of the chest suggested hypostatic pneumonia and bronchopneumonia. The abdomen was moderately distended and the test of the stool was strongly positive for blood. Death occurred early on October 22.

At autopsy the cranial contents were not examined. The ribs were found to be very brittle and porous; there was a moderate hypostatic hyperemia of the lungs, a subacute bronchitis and tracheitis, marked fatty change of the liver and kidneys, moderate hyperplasia of the spleen, moderate fatty changes of the lining of the aorta, and moderate ascites. A section from the sternum was decalcified, fixed and examined. There was almost a complete absence of pregranulocytic elements. The centers for red cell formation seemed normal.

In smears from the lesions in the mouth, October 13 and October 15, gram-negative and gram-positive cocci and gram-negative rods were found. In cultures from the throat, October 13, gram-positive diplococci were grown. Cultures of the blood, October 13, yielded staphylococci; October 15, long chained streptococci; October 16 and October 19, Bacillus coli. The patient's blood, October 15, was injected intraperitoneally into two guinea-pigs but after a month's time had had no bad effect on them.

## COMMENT

This was evidently a true agranulocytic angina. Cultures from the blood yielded a variety of organisms. The sensitivity to pineapple suggests that, as has been noted by Pepper,[1] allergy may be of etiologic significance. Of interest were the calcified deposits on the frontal bones, an exostosis of the hard palate and calcium-like deposits in the sloughs from the mouth, all of which suggested disturbance of the calcium metabolism. The appearance in the blood of granulocytes on the fifth day following the administration of calcium gluconate suggests that this agent may be of therapeutic value. Its use was suggested by the work of Tunnicliff,[2] who has demonstrated, following its administration to rabbits and to a man, an increased phagocytosis by leukocytes in the blood.

## Clinical Notes, Suggestions and New Instruments

### HEALING OF COCCIDIOIDAL GRANULOMA LESION FOLLOWING MEDICINAL THERAPY

Howard A. Ball, M.D., San Diego, Calif.

The reports of results of medicinal therapy in cases of coccidioidal granuloma have been disappointing. Because of the effect of iodides in other fungous diseases, probably the method most extensively used in the earlier cases was the internal administration of iodides. The results were not striking. Recently Chipman and Templeton[1] reported improvement under oral and intravenous iodide therapy but failed to obtain healing. Their results with antimony and potassium tartrate (tartar emetic) were disappointing, although its use seemed wise following the reports of Guy and Jacob[2] and of Tomlinson and Bancroft.[3] The latter investivators use local roentgen therapy as well as antimony and potassium tartrate intravenously, so that it is entirely impossible to assign therapeutic values properly, particularly since x-rays have been accorded beneficial effects by earlier workers. Chemotherapy in the form of copper, arsenic or thymol has been disappointing in its results.[4] Coccidioidin has not been proved to possess merit.

A goodly percentage of the few cured cases on record must be attributed to radical surgical removal of the offending lesion or lesions. Unfortunately, the majority of cases are not suitable for this method of treatment. The disease is ordinarily so disseminated that curative medicinal means must be sought, or the disease will continue to present a rather hopeless outlook.

Perhaps it would be well to establish an arbitrary time period within which no case can reasonably be considered cured, at the same time recognizing that cases may exceed such a period and then exhibit a recurrence or extension of the process. That such a time period has been of considerable help in evaluating forms of therapy, in cases of malignant disease, will scarcely be denied. In twenty-seven of the fifty cases of coccidioidal granuloma studied by Evans and Ball,[5] in which the total duration of the disease was known, an average duration of nine and one fourth months was obtained, the longest time being sixty-two and one half months. Beck[6] records a case of generalized infection lasting seven years and terminating fatally. It would seem that a period of two years should elapse during which time no clinical manifestations of the disease are evident, before a case can reasonably be considered cured.

The case to be reported was submitted to a method of attack previously untried. Fortunately, we were dealing with a single lesion, but in a situation not amenable to surgical eradication. Surgical procedures were carried out on two occasions with no apparent benefit, with the possible exception that they prepared the lesion for a more direct attack with medicinal agents.

That many fungous diseases are cured by iodide therapy is a well known fact. That coccidioidal granuloma has not so responded to iodide therapy does not mean that the organisms may not be susceptible to iodides, but only that they are not susceptible to the concentrations attained by the forms of administration ordinarily employed, chiefly oral.

It was decided in the present case to attempt to secure a higher concentration of iodine and iodides in the vicinity of the lesion. Because of the relative insolubility of iodine in water, and the irritating nature of an alcoholic solution to an open wound, it was decided to prepare a solution of 5 per cent potassium iodide, which was then saturated with iodide crystals. On assay, this solution was found to contain 39.6 Gm. of free molecular iodine per hundred cubic centimeters of solution at room temperature. This falls just short of being a 40 per cent solution of iodine.

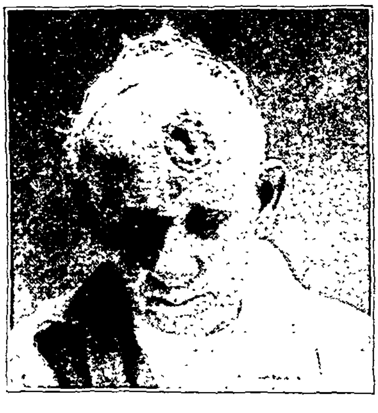

Fig. 1.—Appearance of lesion, July 11, 1931, before applications of iodine. Culture was positive at this time.

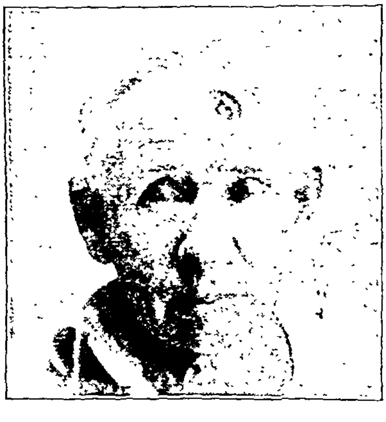

Fig. 2.—Appearance, Nov. 3, 1931, after three and one-half months of iodine application.

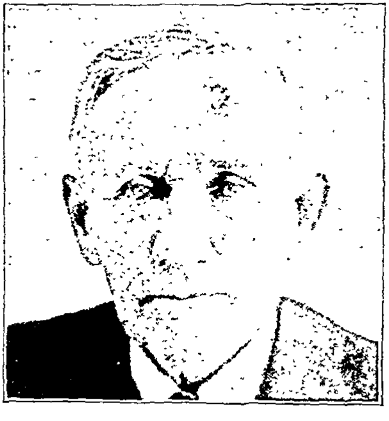

Fig. 3.—Complete healing, Jan. 15, 1932. Note depression due to absence of frontal bone in this area.

This was applied in the form of continuous or intermittent wet dressings, with surprisingly little irritation, and sodium iodide was administered by mouth in doses of 25 minims (1.5 cc.) three times daily.

The rapidity with which the granulations melted away was remarkable. Roentgen examination revealed a filling in of bone in an area previously shown to be partially destroyed. The skin showed a wide zone of erythema, which was assumed to indicate the extent of the iodine absorption. From this point healing was slow, and this was later attributed to the strength of the iodine solution because, after withdrawal of the local applications, healing occurred more rapidly. The time consumed in this form of treatment was approximately six months, when complete healing of the lesion occurred.

[6] Beck, D.: California Dept. of Pub. Health, Special bull. 57, 1931, p. 19.

The apparent success attending the treatment of this case would seem to warrant its trial in other cases. The incision of cold abscesses and irrigation of the cavities with such a solution are suggested, though, with such a strong solution of iodine, toxic effects must be anticipated. Other methods of application will suggest themselves.

### REPORT OF CASE

J. F., a white man, aged 66, an elevator operator, was ill with "pneumonia" in December, 1930. In January, 1931, he noticed what he thought was going to be "a pimple" high on his forehead within the hair line. This was painless and very gradually increased in size during the next few months, when he consulted a physician because it interferred with the satisfactory wearing of a hat. A roentgenogram of the skull showed a destructive lesion in the frontal bone.

Incision of the swelling and curetting of the bone were done, May 10, by Dr. W. J. Ryan. Dr. E. H. Ruediger of the Mercy Hospital rendered a diagnosis of coccidioidal granuloma, from histologic examination of tissue removed at operation.

The lesion drained considerably, and a roentgenogram of the area taken early in June showed an extension of the process in the frontal bone. The bone was again curetted, June 14, and a rubber drainage tube placed. Five days following the second operation, the patient entered the San Diego County General Hospital.

The tube was removed and the wound rapidly filled with granulation tissue. A positive culture of Coccidioides immitis was obtained from the exudate. The appearance, July 11, 1931, is shown in figure 1. The method of attack as outlined was decided on and was actively begun on this date. Saturated solution of sodium iodide was given by mouth in 15 minim (1 cc.) doses three times a day. This was increased to 25 minims and was administered throughout his stay in the hospital (four months). Local applications of potassium iodide (5 per cent) saturated with iodine were used as continuous wet dressings at first and, later, applications three and two times a day until November 3, when it was first discontinued.

Figure 2 exhibits the appearance of the wound at this time. Healing of the wound occurred more rapidly after the discontinuance of the iodine applications. When the size of the ulcer was reduced to a diameter of 2 cm. and while 1 per cent copper sulphate dressings were being applied, several small ulcers occurred in the new skin over the healed area, suggestive enough in appearance to cause the resumption of the external iodine treatment. A prompt healing of the ulcers occurred. Intermittent iodine applications were continued and the lesion was finally healed completely, Jan. 15, 1932 (fig. 3) and has remained so since that time.

The patient has returned to work and feels perfectly well. At no time was his general physical condition impaired. Roentgenograms of the chest have never demonstrated an active pathologic process.

### COMMENT

It would seem justifiable to conclude that Coccidioides immitis is probably sensitive to iodide therapy provided the concentration of iodine is sufficiently great in the vicinity of the organisms, and in this respect it is only quantitatively different from other pathogenic fungi.

The recurrence, while under copper sulphate dressings, of ulcerating lesions in areas previously healed, would tend to throw some doubt on the efficacy of copper or its sulphate in the control of this condition. This is in harmony with unpublished observations I have made on the effects of copper treatment in these cases.

The results in this case would seem to warrant a therapeutic trial in other suitable cases.

A period of two years must elapse, free from evidence of active disease, before I shall consider this case as probably cured.

The unified method of treatment with iodine and iodides makes no other conclusion possible than that they are therapeutically potent agents in this disease.

North Front Street.

# ASTHMA FROM FOOD ODORS

Samuel M. Feinberg, M.D., and Philip L. Aries, M.D.
Chicago

The ingestion of various foods as a frequent specific cause of asthma has been well known for many years. It is less known, however, that some of these foods give off volatile substances, especially during the process of cooking, that are capable of arousing attacks of asthma. The literature contains rather meager references to this subject. In Coca's recent book the following statement is pertinent: "Although fish usually acts as an ingestant, it is not uncommon to find that the mere odor of it in the room, particularly when it is being cooked, may induce asthma in the markedly sensitive child."

The following cases are illustrative:

Case 1.—E. W., a white woman, aged 43, seen by us, Dec. 4, 1928, complained of attacks of cough and dyspnea occurring during the past six months. These spells usually came on about 1 : 30 p. m. on Tuesdays and Fridays. The patient worked at a cafeteria and thought that the odor of scalding shrimps was responsible for the attacks. On further inquiry it was found that it is the custom at this cafeteria to cook shrimps on the days mentioned. The presence of shrimps after they were cooked did not upset her. She had never eaten shrimps. She had a sister who had asthma.

The patient was well nourished. Examination of the chest gave results that were within normal. The blood showed: hemoglobin, 85 per cent; erythrocytes, 3,770,000; leukocytes, 4,500, and no eosinophils. Roentgen examination of the chest was essentially negative. The urine and sputum were normal. The basal metabolic rate was —6 per cent. Cutaneous tests with all available protein extracts were negative, except with the extract of shrimp. The latter gave a + + reaction (moderate size wheal with erythema and itching) on three different trials.

Feb. 9, 1929, the patient reported that shrimps were being cooked in the basement and that she had no trouble. A follow-up report, Feb. 7, 1932, showed that she had had no asthma in over three years, since she was careful to keep away from the room where shrimps were prepared.

Case 2.—C. F., a girl, aged 6 years, seen by us in September, 1930, had suffered frequently from asthma attacks since the age of 2. Many attacks were of a severe nature, lasting from seven to ten days. A cough persisted between these attacks. At times asthma was associated with an infection of the upper respiratory tract. The family history was negative for allergy. During infancy the child had had eczema and chickenpox. The tonsils were removed at the age of 5, after which the attacks of asthma and the respiratory infections were less frequent.

Examination showed slight underweight, and the presence of wheezing râles and dyspnea during an attack. No other abnormalities were noted. The urine and stool were normal. The Pirquet and Schick tests were negative. Cutaneous tests gave strongly positive reactions to pea, bean, lentil, almond and cocoa. There were moderate reactions to string bean, kidney bean, squash, oyster, butternut, peanut, fig, plum and cottonseed.

By elimination it was soon found that peas, beans and lentils were the foods responsible for the attacks. Paroxysms of asthma and urticaria followed the deliberate ingestion of these foods. After they had been eliminated from the diet the parents observed that the child would get an attack of asthma whenever peas, beans or lentils were being cooked in the home. Further cooking of these vegetables was stopped and care was taken to keep the child away from other homes where there was a possibility of exposure to these odors. Under this management there have been no attacks in the last seventeen months.

Case 3.—S. L., an Italian woman, aged 46, seen by us in February, 1930, had had asthma for eight years. The attacks, which had at first lasted only two or three hours, now were a few days in length. She thought that the attacks were precipitated by colds. The past history was insignificant and there was no family history of allergy.

The patient was well nourished. There were wheezing and sonorous râles. No other noteworthy physical observations were obtained. A roentgenogram of the chest showed no

---

From the Allergy Clinic of the Northwestern University Medical School Department of Medicine.

changes. The electrocardiogram showed a slurring of the QRS deflections and some left axis deviation. Skin tests resulted in very marked positive reactions to bean, kidney bean, string bean, pea, black-eyed pea and lentil. There was less marked reaction to hazelnut, fig and wheat globulin.

Following the skin tests the patient gave the information that she could distinctly associate the eating of beans and peas with attacks of asthma. These seizures come on about half an hour after ingestion. She also stated that if she cooked any peas or beans the odor from these gave her an attack within half an hour. If she visited her mother-in-law when any of these vegetables were being cooked, an attack ensued. Lately she had persuaded her mother-in-law to cease cooking peas and beans.

Intradermal tests with extract of peas gave a definite reaction with as high a dilution as 1 : 10,000,000 but failed to react with 1 : 100,000,000. A passive transfer with the patient's serum to the skin of a nonsensitive individual was made. Two days later the sensitized site gave a positive reaction with intradermal injection of pea extract up to 1 : 10,000 dilution. To demonstrate further the volatile nature of the reacting substance, the following experiment was made: A flat dish containing 15 cc. of Coca solution was exposed for half an hour at a distance of 30 inches from dried peas cooking in a pot. Another dish of Coca solution was exposed at a distance of 5 feet from the cooking peas. Both solutions were filtered through Berkefeld filters and tested intradermally on the patient. The first gave a definite reaction, the second a faint reaction. Controls with Coca solution and a solution exposed to other cooking vegetables to which the patient was not sensitive gave negative reactions.

### COMMENT

The cases reported are instances of sensitiveness to volatile substances given off by food (cooking). We have similar cases in which the reaction consists of a rhinitis. It is suggested that this etiologic factor in asthma and other allergic conditions may be more frequent than we realize since in the majority of instances the association of the attack with a specific substance is not apparent to the patient. We realize that the rather common complaint of many individuals that certain odors produce certain undesirable reactions may be in the main psychogenic. We contend, however, that in some it may be actually on an allergic basis. It will be advisable in the future in the case of sensitiveness to food substances not to be entirely content with the elimination of the food from the patient's diet. It is possible that attention to the likelihood of food odors as factors in sensitization may clear up some of the food-sensitive cases that have not responded to ordinary food elimination.

## BULLETS IN THE EAR: REPORT OF THREE CASES

Bert E. Hempstead, M.D., Rochester, Minn.

Judging from reports in the literature, one observer seldom has the opportunity to compare the effects, in different patients, of bullets in the middle ear. Three such cases are reported, and briefly compared, in this paper.

### REPORT OF CASES

Case 1.—A woman, aged 36, came to the Mayo Clinic because of obesity and discharging ears. When the patient was 16 years old and living in Italy, she became infatuated with a youth of 18 years. They decided to get married, but the parents of both objected strenuously. The young people, much disheartened, went into the woods, where they spent the day. Evening came, but home was an undesirable place, and the young woman did not deem it proper to remain in the woods all night with a young man to whom she was not married.

After much consultation, they decided to shoot themselves, reasoning that the most vulnerable spot was the ear. The young man had a small, 0.22 caliber revolver, and two cartridges. He shot the young woman in the right ear, holding the revolver close to the head. She dropped to her knees, but was soon on her feet again, maintaining that she was far from dead. They had not foreseen this, and the question arose as to who was to get the second bullet. The young man decided this easily and shot the young lady in the other ear. Again she dropped to the ground. When he saw she was bleeding from both ears and yet very much alive he became frantic, and rushed back to town, where he drank large drafts of kerosene. Thinking that he was about to die, he told of the experience in the woods. A stomach tube was used and the kerosene removed. The young woman was brought in from the woods. The man was put in jail. When the parents saw that six months' incarceration did not lessen the infatuation of the young people, they relented and had the young man released from prison on the promise that he would marry the young woman and that both would go to the United States. They did this.

The patient was first seen in the Section on Otolaryngology in June, 1927, twenty years after the shooting. She gave the stated history and said that she had had a discharge from the left ear continuously, and from the right ear almost continuously. On seven or eight occasions, the discharge from the right side stopped. This was accompanied by much pain and fever. Hot packs were used. After the discharge had been reestablished, the pain and fever subsided.

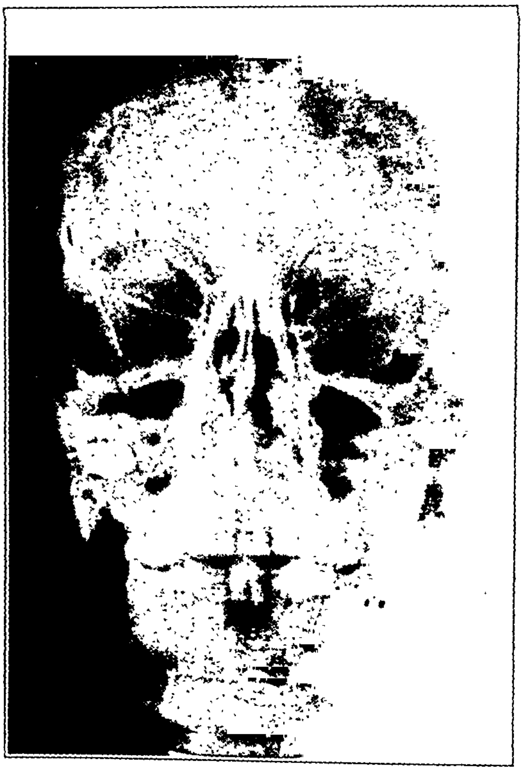

Fig. 1.—Bullets in the right middle ear and in the left upper cervical portion of the spine.

Examination disclosed that the drum of the left ear was destroyed and that there was a thick, mucopurulent discharge. The patient could hear a medium whisper in this ear. Examination of the right ear disclosed that the drum was destroyed and that there was granulation tissue and foul pus in the middle ear. The patient could hear a loud voice ad concham in this ear. The stereoroentgenograms gave evidence that the bullet was in the middle ear on the right side and in the region of the cervical portion of the spinal column on the left. A radical mastoid operation on the right ear was advised and consented to. At the operation, the bullet was found in the middle ear and was removed with some difficulty. The anterior wall of the canal was deficient. There was apparently no injury to the inner wall of the middle ear, and at no time either before or after the operation was there facial weakness or labyrinthine irritation. The typical radical mastoid operation was done.

Convalescence was uneventful. A good cavity was obtained, and hearing improved until a medium whisper could be heard ad concham. The condition of the left ear cleared up under treatment.

---

From the Section on Otolaryngology, the Mayo Clinic.

CASE 2.—A man, aged 29 years, presented himself because of right facial paralysis and deafness in the right ear. Three months before he came to the clinic, he had been shot with a 0.22 caliber bullet, fired at a distance of 40 feet. The bullet entered his head at a point 1 inch in front of the right ear. He did not lose consciousness. The injury was immediately followed by right facial paralysis and profound deafness in the right ear. He had been operated on elsewhere shortly after the accident, in an effort to remove the bullet, but this operation had been unsuccessful.

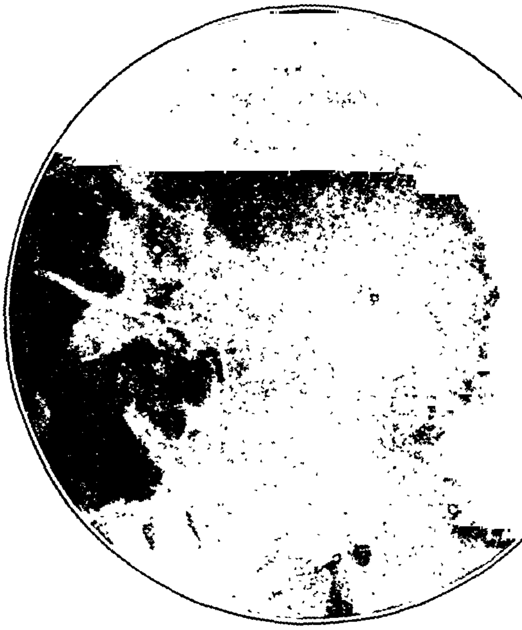

Fig. 2.—Bullet in the right middle ear.

On examination of the right ear when he came to the clinic, landmarks were obliterated, and a note was made that there was something hard behind the drum, or something crowding the drum from above. A roentgenogram gave evidence that the bullet was in the middle ear. The mere presence of the bullet was giving no symptoms, and it was deemed advisable to disregard it for the time being. However, in an attempt to correct the facial paralysis, end-to-end anastomosis between the proximal portion of the spinal accessory and the distal end of the facial nerves was made. The final results of this operation were determined later, as will be explained.

Five years after the accident, the patient began to have pain in the right ear and a foul discharge from it. The condition did not respond to the treatment given it, so he returned to the clinic and a radical mastoid operation was performed. The bullet was found in the posterior inferior portion of the middle ear. Because of the erosion, it was thought best to open the labyrinth after the method of Hinsburg. Convalescence was uneventful. Function of the facial nerve had returned to a considerable extent.

Fig. 3.—Deformed bullet removed from mastoid. The illustration is about one-fourth larger than the bullet, which weighed 76 grains.

CASE 3.—A woman, aged 26, came to the clinic because of pain in the right ear and mastoid. She gave a history of having been shot nine years previously, just below the right nostril. There had been bleeding from the right ear, but with irrigations this had cleared up in one month. No effort had been made to find the bullet.

There had been no further symptoms until six months before the patient presented herself for examination. At that time she complained of sharp pains in the head and neck. Her dentist had removed some teeth, but only a few days' relief had been afforded. The ear then had commenced to discharge and the pain had increased. On her arrival at the clinic, her temperature was 101 F. and codeine was necessary to relieve the pain.

Examination revealed a very narrow canal, a thin discharge, under pressure, and tenderness present. Roentgenograms indicated that the bullet was in the middle ear.

A radical mastoidectomy was performed. The bullet was found at the inner end of the external canal and partly in the middle ear. The inferior wall of the canal was eroded. There was a large cholesteatoma in the middle ear and attic. The bullet, together with the cholesteatoma, was removed. There had been no injury to the facial nerve or semicircular canals. The patient still retained some hearing. Convalescence was uneventful.

### COMMENT

In case 1, the foreign body caused a discharge almost immediately and gave more or less trouble all the time. In case 2, the middle ear tolerated the bullet five years before a discharge was set up. In case 3, more than eight years elapsed before the foreign body commenced to give trouble.

## *Special Article*

# VITAMIN $B_1$ IN RELATION TO THE CLINIC

GEORGE R. COWGILL, PH.D.
Associate Professor of Physiological Chemistry, Yale University
NEW HAVEN, CONN.

[EDITORIAL NOTE.—The following article is one of a series on the Present Status of the Knowledge of Vitamins, prepared under the auspices of a committee composed of Morris Fishbein, chairman, Lafayette B. Mendel and Julius Hess, representing a joint committee of the Council on Pharmacy and Chemistry and the Committee on Foods. These articles have been considered by the Council on Pharmacy and Chemistry and by the Committee on Foods and are published under their auspices. The opinions expressed are those of the authors and not necessarily the opinions of the Council on Pharmacy and Chemistry or the Committee on Foods.]

When considering the application in the clinic of the experimental work of physiologists concerning the antineuritic vitamin, it is advantageous to distinguish between the state of extreme deficiency of this accessory food factor as contrasted with that in which there is only a moderate shortage of this vitamin. Beriberi may be taken as the prime illustration of the former condition; its syndrome is quite well defined, a fact that is of great aid to an accurate diagnosis. Quite a different state of affairs characterizes a moderate lack of antineuritic vitamin. In such cases the picture is not clear-cut but rather confused, and in consequence of this there may be considerable difference of opinion regarding the significance or even the existence of various alleged features of the syndrome. Obviously, then, progress in this field must necessarily be slow, and every step forward must be taken with proper scientific caution; the need for preservation of an open-minded attitude with respect to developments in this field of activity is very great.

Many of the efforts now being directed toward clinical application of the facts discovered concerning vitamin $B_1$ are essentially preventive in nature rather than curative. It is not an exaggeration to say that the greatest advance that can now be made with respect to conquering beriberi lies not in the treatment and cure of this condition, for these problems have really been solved, but in the development of some plan by which governmental and social forces can be brought to bear on the prevention of beriberi in those parts of the world where this disease is a veritable scourge. From time to time, students of this problem have suggested measures aimed chiefly at reducing the consumption of polished rice in the Far East, where beriberi is endemic.[1] Numerous animal tests have been made in an endeavor to arrive at some fairly simple standard of rice composition that might be useful in framing laws aimed at curbing the traffic in too highly polished rice.[2] If any really satisfactory plan could be devised that would accomplish a marked reduction in the use of white rice and an increased consumption of certain other foods in the face of the poverty and ignorance that prevail among the masses of the Far East, this discovery would, in my opinion, be one of the first order in its value to mankind.

Similarly, the problem presented by a moderate shortage of antineuritic vitamin is to a considerable extent one of preventive medicine. Two schools of thought have contributed to the discussion of this problem. Some clinicians[3] maintain that the possibility of vitamin $B_1$ deficiency occurring to any appreciable extent under the conditions of dietary habits and regimens prevailing in the United States has been greatly exaggerated; these clinicians insist that mere regulation of the diet, substitution of vegetables and fruits for much of the highly milled components of the American dietary, suffices as a therapeutic measure and that it is not necessary to use special concentrates of vitamin B in the clinic except perhaps in manifest beriberi. This attitude toward the problem is easily understood when one appreciates the paucity, until recently, of suitable clear-cut clinical evidences of the need for antineuritic vitamin, except in cases of obviously extreme deficiency, such as is seen in beriberi.

In contrast to this view, one may cite the position of the clinician who realizes that (1) the law of the minimum is involved in the preservation of the healthy nutritive state, (2) because of faulty gastro-enteric function there may be a failure to utilize a large enough fraction of the vitamin ingested, (3) because of obstructive conditions there may be great difficulty in taking sufficient nourishment by mouth and a condition of vitamin deficiency may result, (4) the period of vitamin shortage which an individual may safely endure is variable, being influenced by several factors, and (5) in cases of doubt with respect to a shortage of vitamin B playing a rôle the test is simple and harmless and consists not merely in regulating the diet—a therapeutic measure that exerts its beneficial effect slowly—but in administering large amounts of the missing factor immediately and thus securing a prompt answer to the question.

Much of the disagreement among clinicians with respect to the importance of vitamin B is doubtless due to failure to appreciate the fact that many of the studies conducted on animals are not quite comparable to those made on man. The investigator working with animals endeavors as far as possible to limit the variables operating in his experiments. The success which attends his efforts in this regard determines to a very large extent how precisely he may state his conclusions and how convincingly he may demonstrate cause and effect relations. In the case of observations to be made on human beings, however, the problem of suitable experimentation is a much more difficult one. A dietary deficiency in a human being is much more likely to be a complicated condition. It is not to be presumed that many persons live on precisely the same diet as, for example, a group of rats used in a nutritional investigation. In all probability the "wet" and the "dry" types of beriberi represent essentially the same deficiency disease with different complications. It is well known that a nutritional edema may be produced experimentally by feeding diets low in protein over extended periods until the concentration of blood plasma proteins falls to an abnormally low level. It is quite possible, although by no means proved as yet, that the edema of "wet" beriberi is due to a shortage of protein and is therefore evidence of a multiple deficiency.

It is obvious that when clear-cut results are obtained in suitably controlled animal experiments, they deserve very careful consideration. Each suggestion from this field of endeavor should be given suitable clinical trial, and final judgment as to the significance of animal experiments to the clinic should be reserved until the results of clinical tests are at hand. For the correct evaluation of the researches there should be cooperation of the physiologist with the clinician.

### BERIBERI: A CONDITION OF EXTREME VITAMIN $B_1$ DEFICIENCY

*Definition and Etiology.*—"Beriberi is an acute or chronic disease characterized by changes in the nervous system and particularly by a multiple peripheral neuritis with an especial tendency to attack the nerves of the limbs, the pneumogastrics and phrenics. Ordinarily the clinical picture of a peripheral neuritis is combined in varying degrees with cardiac disturbances, edema, serous effusions and gastro-intestinal derangements. Exceptional cases occur in which cardiac dilatation and sudden death are the first symptoms observed."[4] The early work and ideas concerning the etiology of this disease are admirably presented in Vedder's monograph. The points of view that have been expressed with respect to the origin of beriberi may be summarized briefly as follows: (1) The disease is essentially an intoxication, (2) it is an infection, and (3) it is due to lack of an essential dietary factor, namely, the substance now called vitamin B (or $B_1$). In the light of the developments in the field of the science of nutrition, especially since 1913, when the word vitamin was introduced, and the application of these observations to clinical medicine, there seems to be little doubt as to the validity of the deficiency disease hypothesis in relation to beriberi. It should be stated, however, that some clinicians, notably among the Japanese, still favor the view that beriberi is an infection.[5] Matsumura and his associates have recently claimed the isolation of a "beriberi bacillus" believed to be responsible for this disease, but Swineford[6] was not able to confirm this in his experience. Many of the arguments advanced by Ogata, by Matsumura and by Nagayo are not essentially different from those discussed by Vedder, who championed the deficiency disease theory. Concerning the thesis that the administration of vitamin B does not always bring about a complete cure of human beriberi and that therefore this disease cannot be essentially a vitamin B deficiency, attention should be called once more to the following points: (1) A complicated rather than a single deficiency may be in part responsible for this result, and (2) even in experimental beriberi in animals this may occur through failure of the vitamin given by mouth to reach the most vitally situated lesions soon enough, because of gastro-enteric disturbances. Observations in animals show that the time required for the vitamin to exert its curative effect depends to a considerable extent on the way the remedial agent is administered. Absorption from the gastro-intestinal tract is rapid enough in moderately advanced cases but too slow when the deficiency is of the most advanced type, in which case parenteral injections must be employed in order to save the animal. More extensive trials of parenteral administration of vitamin B in cases of human beriberi should contribute much toward the solution of this controversy.

*Incidence in the United States.*—Although the incidence of beriberi is very high in the Far East, this disease is of comparatively rare occurrence in the United States. Discussion of the prevalence of beriberi will be limited to its occurrence in North America. Because of its rarity, relatively few clinicians in the United States ever have the opportunity for observing beriberi. Most of the cases in adults that have been reported in the medical literature of this country have occurred among immigrants from the Far East [7] and individuals who have subsisted on definitely restricted diets either voluntarily,[8] or because they were inmates of institutions,[9] or because of economic and other factors.[10]

*Pathology and Diagnosis.*—According to Vedder's review of the pathology of beriberi in man, the chief finding is a multiple peripheral neuritis. The most recent contributions to this subject from the field of animal experimentation [11] confirm this and give further support to the view that human beriberi is essentially a vitamin $B_1$ deficiency. These observations indicate the important points that must be considered when making a differential diagnosis. The condition must be distinguished from other types of peripheral neuritis, notably those due to poisoning with alcohol and with metals. The history is of assistance here. When examining the patient with the view to determining whether the diet has been adequate, it is important to find out not only whether the individual partakes of those foods known to contain appreciable amounts of vitamin $B_1$ but how much he eats, because recent studies on animals indicate the great importance of the quantitative as well as the qualitative aspect of this matter. The experience of Goldberger in his study of the diet factor in relation to pellagra illustrates this point. Minot [12] also has called attention to this fact, and my experience with a recent case of beriberi in the New Haven Hospital impressed on me the importance of care in this regard.

Recent animal studies [13] have shown that what was formerly called vitamin B really consists of at least two physiologically active factors, the antineuritic substance (also called vitamin B, or $B_1$, or "antiberiberi" vitamin) and the heat-stable "antidermatitis" vitamin $B_2$ (or G, or "antipellagra" factor). It is interesting, therefore, to find that clinical cases of pellagra combined with beriberi have been reported.[14] The fact that such a condition is not encountered oftener probably finds its explanation in the diets used. The common beriberi-producing ration of the Far East is chiefly polished rice and fish. The rice is deficient with respect to both of the vitamin B factors, namely, the antineuritic substance and the pellagra-preventive factor, but the fish muscle contains fair amounts of the "antipellagra" substance. Corn meal, which is the staple food of the pellagrins in the Southern states, is low in its content of the pellagra-preventive vitamin but, when eaten in large amounts, supplies adequate quantities of the antineuritic substance.

It is an interesting fact that beriberi occurs much more frequently in men than in women.[15] If the results of recent studies on animals [16] can be legitimately applied to human beriberi, then this difference in incidence related to sex is to be attributed to the greater metabolic rate, activity and food consumption characteristic of most males.

*Beriberi in Relation to Fevers and Gastro-Intestinal Disturbances.*—There are reports in the literature of the occurrence of beriberi following prolonged fevers and gastro-intestinal disturbances. Of the fifty-two cases described by Bentley,[15] twenty-eight appear to have been the sequel of recurring malaria or dysentery and allied conditions. Bentley's observations were made in Java on persons who, in the light of my recent studies aimed at evaluation of human dietaries with respect to content of vitamin $B_1$, were subsisting on rations barely sufficient or "borderline" in character, and in whom, therefore, there was only a small factor of safety against the development of beriberi. Yacoub [17] reported three cases that followed relapsing fever, and in these instances there was a prolonged feeding of condensed milk, a food which, according to recent animal tests, contains appreciable amounts of the heat-stable "pellagra-preventive" substance but relatively small quantities of antineuritic vitamin. Nineteen per cent of Walshe's cases,[18] observed in Egypt, showed a previous history of malaria. The association of malaria with beriberi occurs so frequently in Brazil that the physicians of that country[19] have been led to favor the view that beriberi is to a considerable extent an infection. The same attitude was taken by Cannon,[15] who, in reporting his cases in Hong Kong, stated that "the dry and dysenteric beriberis are really camouflaged forms of malaria, as proved by the invariable findings of the specific malarial parasites on careful examination." On the other hand, the observations of Lovelace[20] and Walcott[21] made in Brazil clearly support the view that the beriberi occurring in this region is a dietary deficiency disease as elsewhere. In the absence of vitamin B studies in animals, these conflicting reports would prove rather difficult of interpretation; when viewed in the light of the experiments that my associates and I[22] have conducted, they find a reasonable explanation. The experiments just referred to were performed on four different species of animals. The results support the view that the amount of vitamin B required by the organism is related to the amount of food consumed, or the total metabolism; when the animal is restricted to a diet deficient in vitamin B, and its metabolism is increased by forced exercise[23] or by the administration of thyroid tissue,[24] signs of vitamin B deficiency appear much sooner than otherwise. The indications from such studies are that more vitamin B is required whenever the metabolic rate is raised. It is reasonable to expect, therefore, that individuals subsisting on diets the vitamin B contents of which are too small or just barely sufficient should be brought to a condition of extreme vitamin B deficiency when subjected to a prolonged regimen of fever or of heightened metabolism.

In the same way one may explain the frequency with which beriberi has been shown to follow a prolonged siege of gastro-intestinal disturbance, such as is represented by dysentery. Observations on animals[25] have shown that the feces contain appreciable amounts of vitamin B. This fact is so important that coprophagy on the part of the experimental animals must be prevented whenever foods are being assayed for their content of the antineuritic vitamin, if the results are to be at all quantitative. Much of the vitamin present in the intestinal excreta is doubtless the result of the activity of certain strains of bacteria,[26] but some of it may have originated in the food ingested and have escaped absorption in its passage through the alimentary tract. At the present time, practically nothing is known concerning the locus of absorption of this vitamin in the intestine. Cowgill, Rosenberg and Rogoff[27] were able to show that in dogs given large volumes of water daily, signs of lack of vitamin B appear much sooner than when the animals are allowed water ad libitum. It is not unreasonable to attribute the development of beriberi in cases of prolonged diarrheas of whatever cause to failure of the individual to absorb a sufficient fraction of the ingested vitamin to meet the needs of the organism; this failure of absorption becomes more important as a contributory cause of beriberi when the amount of vitamin B in the diet is low or only barely sufficient; in such cases the factor of safety against beriberi is small.

To what extent gastric achlorhydria is a factor favorable to the development of beriberi or is the result of this disease, it is impossible to say at the present time. This condition occurs often in beriberi, but not invariably, and has been reported to develop in animals fed diets lacking vitamin B.[28] Wohl[29] has described a case as "avitaminosis in the course of diabetes . . . with symptoms and lesions of beriberi predominating." Minot[12] reported having seen two cases of diabetes associated with peripheral neuritis and achylia gastrica, "whose symptoms slowly improved upon taking large amounts of a concentrate of yeast," and states that "one must wonder if achylia gastrica is not a factor that can inhibit the utilization of both the P. P. (pellagra-preventive) and antineuritic factor of vitamin B." Gastric ulcer would seem to be another type of gastric disturbance likely to lead to beriberi or to a milder form of vitamin B deficiency because the treatment involves essentially a marked restriction of diet; prolonged subsistence on a ration of cream and other foods valuable because they do not stimulate gastric secretory processes certainly operates to favor the development of a condition of vitamin B shortage. The duration of this dietary treatment is obviously an important factor here.

Beriberi has also been reported as related in some way to jaundice. In a study of forty cases of beriberi, Walshe[18] noted such an association but after due consideration of his data decided against the jaundice being related etiologically to beriberi. It is possible to take the view that the jaundice in such cases represents a complication in no way related to beriberi. One may also consider the jaundice as evidence that the alimentary functions are not normal and that the development of beriberi is favored by the gastro-intestinal disturbance, especially when the diet is only barely adequate with respect to its content of vitamin B.

To the careful clinician the numerous conditions predisposing to the development of vitamin B deficiency that have just been discussed will suggest others as worthy of attention. Obstructive states, in which intake of sufficient nourishment is difficult, may be mentioned. Chronic wasting diseases constitute another category of interest.

*The Heart in Beriberi.*—Students of beriberi have long recognized cardiac manifestations as important elements of the syndrome of this disease. There is a definite hypertrophy, chiefly of the right side of the heart. Irregularity, extrasystole, flutter and fibrillation do not occur. The usual heart remedies are without effect. According to Vedder, "exceptionally, cases occur in which cardiac dilatation and sudden death are the first symptoms noted." Sudden death has also been observed in dogs subsisting on vitamin B-deficient diets.[30] The older explanation of this sudden fatality has been that it is due to an extensive degeneration of the vagus nerves. The recent studies of Aalsmeer and Wenckebach[31] support another explanation. These authors believe that the fundamental process in beriberi is water retention and consequent swelling of certain vital tissues, especially the heart and striated muscle. They make the point that the cardiac dilatation may be detected long before the first manifestations of polyneuritis. This observation should be of great significance to clinicians, particularly those specializing in cardiac disorders. The effect of the administration of vitamin B on the beriberi heart is striking. There is a rapid return of the heart to normal size, this being accompanied by a marked secretion of urine. Wenckebach[32] cites the work of Rigler, seeming to show that the highly purified vitamin B preparation of Jansen and Donath[33] acts as a heart hormone or "automatin." Further research along this line will be awaited with interest.

*Infantile Beriberi.*—In the Far East the incidence of infantile beriberi is very high. The great prevalence of this disease among rice-eating people is doubtless due to at least three important facts: 1. During the first six months of its life the human infant subsists almost entirely on milk and is therefore in the category of individuals who live on a restricted dietary. 2. The amount of antineuritic vitamin B present in the milk has been shown to be dependent primarily on the quantity ingested by the mother.[34] 3. Most of the diets consumed by those who use white rice as the staple food are deficient or just barely adequate with respect to content of antineuritic vitamin; under such dietary conditions the amount of vitamin ingested by the mother above her own immediate requirement and thus available for transfer to her milk is small, and as a consequence the milk is deficient with respect to the vitamin.

Moore and Brodie[35] have reported an instance of hemorrhage in a new-born infant, which presented pathologic evidences of beriberi. The mother's diet during the prenatal period was markedly deficient in antineuritic vitamin. In commenting on this case the authors stated that "diets restricted by poverty, pernicious vomiting, diabetes or other causes need careful scrutiny from the standpoint of vitamins." In order to elucidate more fully the relationship of vitamin B in the maternal diet to infantile beriberi, experiments were also performed on rats,[36] with results abundantly confirming the clinical observations. Additional confirmatory evidence may be cited in the work of Sure[34] and of others.[37] The implications of these observations to the clinician are obvious. Vitamin B should be administered to the mother during the gestation period as a protective measure and to both the mother and the infant after parturition. Careful regulation of the diet may be a sufficient therapeutic measure to adopt during the prenatal period in most cases, but when complications are present it may be advisable to administer concentrates of the antineuritic vitamin. When severe symptoms of beriberi have already developed in the infant, they may be obviated almost miraculously by administration of suitable amounts of a concentrated form of vitamin B.

### OTHER POSSIBLE (?) CONDITIONS OF EXTREME VITAMIN B DEFICIENCY WORTHY OF CONSIDERATION

There are many conditions besides beriberi in which injury to the nervous system is a prominent feature of the disorder. Spinal cord lesions are found in advanced cases of pernicious anemia. Lesions in the brain have been described as characteristic of human pellagra. Gildea and his associates[38] reported the appearance of lesions described as "disseminate sclerosis" in the spinal cords of dogs fed diets deficient chiefly in antineuritic vitamin B. Zimmerman and Burack[11] disagree with Gildea and his collaborators as to the interpretation of the histologic preparations obtained by the latter. It would be generalizing too widely and on too uncertain data to say that in all these nervous disorders lack of antineuritic vitamin is an etiologic factor. On the other hand, in the face of the uncertainty as to what part is played by this vitamin in the nutrition of the nervous system, it seems justifiable to advocate administration of the vitamin in such cases, especially when this therapeutic measure is so easy to carry out and cannot do any harm. It is of interest to learn that one clinician is experimenting with vitamin B therapy in cases of delirium tremens. In this connection it is pertinent to cite the claim of both Kimura[39] and Lhermitte[40] that, so far as the central nervous system is concerned, their histologic pictures obtained from cases of human beriberi are indistinguishable from those of toxic polyneuritis. This is a field of investigation worthy of careful cultivation by the clinician.

### CONDITIONS OF SLIGHT AND MODERATE SHORTAGE OF VITAMIN B

*Anorexia.*—In the introductory remarks I called attention to the lack of agreement among clinicians as [illegible] of vitamin B in conditions other than [illegible] which represents essentially an extreme deficiency of this accessory food factor. Evidence showing the importance of an adequate intake of this vitamin not only in preventing beriberi but in the maintenance of a normal voluntary intake of food has come from researches on animals. Karr[41] and Cowgill[30] have been able to demonstrate in dogs a relation between vitamin B and the urge to eat. A description of a representative experiment follows:

> The animal is fed an artificial diet adequate in all known respects except for vitamin B. Over a variable period, depend-

ing on the previous nutritive history of the animal, the dog consumes all the food offered within a few minutes. Then anorexia appears; the dog may eat part of the food in the course of a few hours and repeat this behavior for several days. The anorexia may be partial or may become fairly complete. If at any time after the anorexia first appears, a sufficient amount of vitamin-containing material is given, the appetite is restored and the animal eats ravenously the same food that was previously refused.

In the earlier experiments the test substances were placed in the stomach of the animal rather than in the food mixture in order to avoid the possible effect of mere change in the taste of the ration. Later it was found that if the test material was mixed with the food the animal might be induced to eat a small amount. If, however, by eating this small amount vitamin B was not obtained, the anorexia continued. It has even proved possible to restore the urge to eat to vitamin-deficient dogs by intravenous injection of the missing dietary essential.[42] What is most important to remember in this connection is the fact that other dogs, given precisely the same experimental diet plus a daily small but sufficient amount of a vitamin B concentrate, have been maintained in excellent nutritive condition with perfect appetite for the food offered for about a year and a half (540 days).[43]

This anorexia, whatever its complete explanation may be, should be of interest to the clinician. Loss of the urge to eat is generally regarded not as a disease in itself but as a symptom, and this is doubtless the correct attitude to take. It is obvious, also, that loss of interest in food may be the result of the operation of many factors, some psychic and others associated with manifest disease quite unrelated to vitamin B deficiency; it is not logical to assume that administration of vitamin B in such cases will restore the urge to eat. The true significance to the clinician of the results of these animal experiments, however, should be clear. In any case presenting anorexia as an important feature of the syndrome, shortage of vitamin B as an etiologic factor may be readily ruled out by administration of liberal amounts of this dietary essential.

Clinical evidence has already been obtained showing that this condition of moderate shortage of vitamin B does occur in the human species. It has been shown that many marasmic babies have their interest in food and the urge to eat restored by the administration of vitamin B.[44] Newburgh[45] succeeded in increasing the voluntary food intake of a mentally incompetent young woman from about 400 to approximately 2,000 calories a day by the simple expedient of administration of vitamin B. Swineford[6] has described a case diagnosed as mild beriberi resulting from a prolonged siege of typhoid and inadequate nutrition during convalescence. Administration of vitamin B brought about prompt correction of the anorexia and disappearance of the neuromuscular symptoms suggestive of beriberi. It is not unlikely that certain instances of anorexia noticed in convalescents who have subsisted on hospital fare for long periods and who have an unrecognized poor utilization of the vitamin ingested really represent a moderate shortage of vitamin B. This is a field of investigation and clinical trial that presents interesting possibilities.

In this connection it is of interest to cite the observations of Stucky and Rose,[46] who made blood studies in dogs subsisting on vitamin B-deficient diets. Anhydremia was one finding of note. When the vitamin-deficient dogs were given the missing factor they promptly and voluntarily consumed large volumes of water and voided much urine. These observations may have a bearing on the question of the origin of the edema and the anhydremia in "wet" and in "dry" beriberi, respectively. They also suggest that the anhydremia in certain marasmic infants owes its origin in the last analysis to a shortage of vitamin B. The observation of Cowgill, Rosenberg and Rogoff,[27] that this anorexia appears much sooner in dogs given forced administration of large amounts of water daily, suggests, also, that when fluid is given to marasmic babies, vitamin B should be administered at the same time. These are possibilities that must await clinical trial before being accepted in toto.

Hoobler[44] has studied in infants a syndrome described as indicative of lack of antineuritic vitamin. Features of the symptom complex are anorexia, a strange plaintive cry and a certain type of stiffness of the arms, legs and neck believed to be similar to the spastic condition noted in animals suffering from vitamin B deficiency. This condition is readily alleviated by ingestion of sufficient amounts of antineuritic vitamin.

It is obvious that all the conditions that I have cited as favorable to the development of beriberi, i. e., heightened metabolism, faulty gastro-enteric functions, and the like, also operate to bring about a condition of moderate shortage of vitamin B and therefore should be of special interest to American clinicians.

*Restriction of Growth.*—Several investigators[47] have commented on the prevalence of faulty nutrition among children both in this country and in Europe. Until recently it has been difficult to say to what extent a deficiency of antineuritic vitamin is a factor here in limiting growth. Inadequate amounts of calcium and of vitamin A may be playing a greater part. The studies of Morgan and Barry,[48] however, show conclusively that shortage of vitamin B can be a factor in limiting the growth of American school children. When one considers the types of diet that many of the poorer classes are undoubtedly restricted to, especially in such a period as the present world-wide economic depression, the observations of Morgan and Barry become even more significant. Insufficient intake of antineuritic vitamin is probably more serious in children than in adults on account of the child's lower capacity for tissue storage of vitamin reserve and a relatively greater need for this factor to meet the requirements of growth as well as of maintenance. It is especially important to realize that vitamin B is a dietary essential, and therefore care should be taken to see that more than enough of this factor is being supplied at all times both to the growing child and to the adult.

### SOURCES OF VITAMIN B FOR CLINICAL USE

*Foods.*—Alterations in the diet designed to increase the amount of vitamin B furnished to the patient constitute one very important and simple therapeutic measure. Tables showing relative amounts of vitamin B in common foods are available elsewhere[49] and need not be presented here. A few general remarks may be helpful. Yeast and wheat germ are two excellent sources of this vitamin and furnish the starting point for the preparation of many special products that are essentially concentrates of this dietary factor. Among the body tissues containing relatively large amounts are the glandular organs, notably the liver, kidney and brain, all of these being much richer than muscle. The whole grains because of their content of germ contain appreciable amounts, in contrast to the highly milled products such as white flour and degerminated corn meal. Among the fruits and vegetables, tomatoes, raw cabbage, fresh spinach and legumes have been found to contain more than orange or lemon juices, onions, lettuce or cauliflower. In the egg the vitamin is located in the yolk. Milk, although a good source of the pellagra-preventive substance, cannot be rated as containing a large amount of vitamin $B_1$. For this reason it is a valuable therapeutic measure to supplement the infant's formula-milk with some source of the antineuritic vitamin.

*Special Concentrates of Vitamin $B_1$.*—In many cases it is important to combine dietary regulation with administration of special concentrates rich in vitamin $B_1$, in order to secure prompt alleviation of symptoms. Numerous products are now available for this purpose. It is my opinion that whenever any product of this nature is offered for use by the clinician there should be evidence that the material really contains an appreciable amount of the antineuritic vitamin; this evidence may be obtained by animal tests. The wise clinician will insist that such proof be obtained.

At the present time there do not appear to be available in any reasonable quantity concentrates of vitamin B that may with impunity be administered parenterally to human beings. The recent appearance of a case of beriberi in New York City, in which administration of the vitamin by mouth was practically impossible, indicates the importance of having on hand preparations suited for therapy in such contingencies.

**Lissauer's Dementia Paralytica.**—The usual case of dementia paralytica shows at autopsy diffuse atrophy of the cerebral cortex, which is most intense in the frontal lobes and progressively decreases in intensity toward the posterior poles of the hemisphere. Such a distribution of the atrophy is expected from the character of the clinical course, which offers no symptoms or signs of a focal nature. In contrast to these usual cases are the cases which during life show focal signs and at autopsy striking atrophy of certain convolutions. . . . Heretofore, dementia paralytica has been considered only a disease of the cortex, and all lesions found in the white matter have usually been thought to be secondary.—Merritt, H. H., and Springlova, M.: *Arch. Neurol. & Psychiat.* **27:**987 (May) 1932.

# Committee on Foods

The following products have been accepted by the Committee on Foods of the American Medical Association following any necessary corrections of the labels and advertising to conform to the Rules and Regulations. These products are approved for advertising in the publications of the American Medical Association, and for general promulgation to the public. They will be included in the Book of Accepted Foods to be published by the American Medical Association.

Raymond Hertwig, Secretary.

## RECOLAC

A food for infants, containing soluble casein, lactalbumin, lactose, milk salts (all derived from fresh cow's milk), dextrins, maltose, salts, extracts of yeast and wheat embryo, animal and vegetable fats and cod liver oil; the whole so proportioned as to satisfy almost all nutritional requirements of infants; contains vitamins A, B, D and G.

*Manufacturer.*—Mead Johnson and Company, Evansville, Ind.

*Description.*—A food for infants, containing soluble casein (potassium caseinate), lactalbumin, lactose, milk salts, dextrins, maltose, salts, extracts of yeast and wheat embryo, oleo, coconut and cod liver oils; contains vitamins A, B, D and G.

*Manufacture.*—All milk used in the preparation of this product comes under inspection of the Chicago Board of Health and complies with its requirements. On receipt at the factory it is pasteurized by the usual standard "holding" process. The pasteurized milk, almost completely defatted by centrifugalization, is acidified with sufficient dilute phosphoric acid solution to precipitate the casein in small flocks. The casein is permitted to settle and the whey is removed by decantation.

The precipitated casein is washed with water by decantation and made neutral to phenolphthalein with potassium hydroxide solution, whereby the casein is converted to potassium caseinate. Recolac therefore contains potassium caseinate in place of calcium caseinate of ordinary milk.

The separated whey is treated with calcium hydroxide to precipitate the added phosphoric acid and soluble calcium salts of the milk; the precipitate is removed by filtration and centrifugalization.

The decalcified whey and calculated quantities of potassium caseinate, di-calcium phosphate, oleo, coconut and cod liver oils and Dextri-Maltose with vitamin B (essentially maltose, dextrins, extracts of yeast and wheat germ and mineral salts) are combined and homogenized under high pressure to disperse the fat in very fine globules. The homogenized mixture is concentrated under "vacuum" (2 inches of mercury) and dried by a "vacuum" (2 inches of mercury) drum drier method. Recolac, the final dry powder, is packed in tins and hermetically sealed in an atmosphere of nitrogen.

Glass-enamel tanks are used in the preparation of the whey and the potassium caseinate. Great care is exercised in the sanitation of all equipment.

*Analysis* (submitted by manufacturer).—

Reichert-Meissl number of Recolac fat, 2.8

* Calculated from analyses of component ingredients.

*Calorics.*—5.2 per gram; 148 per ounce.

*Micro-Organisms.*—The manufacturer guarantees the absence of pathogenic organisms.

*Claims of Manufacturer.*—Recolac reliquefied to normal dilution of 1 ounce of powder + 7 ounces of water forms a well balanced food for infants who are deprived of breast milk. It may be used as a complemental or supplemental feeding and is particularly desirable for the traveling mother. Recolac keeps well in the sealed can, is readily miscible in water, and is simple to use. The necessary accessory food factors, such as orange juice and cod liver oil, should be used when feeding Recolac.

## PURITY 2 LOAVES IN 1 BREAD

*Manufacturer.*—Purity Baking Company, Decatur and Pana, Ill.

*Description.*—A white bread made by the sponge dough method.

*Manufacture.*—The sponge dough ingredients, patent flour of southwest wheat, water, yeast, malt syrup, lard and a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, are mixed in a high speed mixer. The sponge dough is fermented for from four to five hours, after which are added flour, water, salt, sucrose, dry skim milk and lard to make the completed dough, which is cut into pieces of desired weight. The pieces are fermented for a short time, molded into loaf form, panned, further fermented, baked for from thirty to thirty-five minutes, cooled, and wrapped in wax-paper.

The factory, equipment and storage rooms are kept in strictly sanitary condition.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 34.8 |
| Ash | 0.8 |
| Fat | 1.4 |
| Protein (N × 6.25) | 9.4 |
| Crude fiber | 0.3 |
| Carbohydrates other than crude fiber (by difference) | 53.3 |

*Calories.*—2.6 per gram; 74 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## NICOLET BRAND GOLDEN SYRUP

(85 per cent corn syrup, 15 per cent refiners' syrup)

*Packer.*—D. B. Scully Syrup Company, Chicago.

*Distributor.*—Frank C. Schilling Company, Green Bay, Wis.

*Description.*—A table syrup; a corn syrup base (85 per cent) with refiners' syrup (15 per cent).

*Manufacture, Analysis, Calories and Claims of Manufacturer.*—See these sections for Banner Blue Golden Syrup with Cane Flavor (THE JOURNAL, March 5, 1932, p. 817).

## LOUDON BRAND TOMATO JUICE

*Manufacturer.*—The Loudon Packing Company, Terre Haute, Ind.

*Description.*—Canned tomato juice; retains in large measure the vitamin content of the raw juice used; contains a small amount of added salt.

*Manufacture.*—The tomatoes are obtained from neighboring territory and are graded and inspected on sorting tables. Only the ripe better quality tomatoes are used for the juice. Most of the tomatoes are canned within eight to twelve hours after picking, the maximum time being eighteen hours.

The tomatoes are conveyed in sluices to squirrel cage washers and subjected to high pressure sprays which break up overripe or defective tomatoes, enabling their removal on the sorting belt. The washed tomatoes are carefully inspected, sorted and trimmed on conveyor belts, and bad tomatoes are discarded. The selected tomatoes are lightly scalded in a steam box and macerated in a water vapor atmosphere in cyclones which express the juice. The juice flows to holding tanks and is pumped in enamel lined pipes to "finishers," where it is forced through fine screens to eliminate coarse pulp. The juice outlet line from the holding tank extends to the bottom of the tank to avoid foaming and introduction of air, the tank never being emptied to a point at which the outlet line is exposed to the air. From the "finishers" the juice is pumped through enamel lined pipes to a "vacuum" tank, into which it is sprayed to expose a maximum surface to the "vacuum" of three inches mercury pressure. The juice is homogenized to prevent separation of insoluble matter, is conveyed into the bottoms of preheating tanks to avoid foaming and introduction of air, is quickly heated to 87 C., and, after salt is added, is automatically filled into cans at about 85 C. After sealing, the product is pasteurized (final temperature, 85 C.), quickly cooled and stored.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 95.1 |
| Total solids | 4.9 |
| Ash | 0.9 |
| Chlorides as NaCl | 0.7 |
| Fat (ether extract) | 0.1 |
| Protein (N × 6.25) | 1.0 |
| Reducing sugars as invert | 2.3 |
| Sucrose | none |
| Crude fiber | 0.2 |
| Carbohydrates other than crude fiber (by difference) | 2.4 |
| Acidity as citric acid | 0.3 |

*Calories.*—0.2 per gram; 6 per ounce.

*Vitamins.*—The use of mature tomatoes, the careful factory control, the continuous method of manufacture, the exposure of the fruit juice to an atmosphere of steam only in the factory equipment, and the withdrawal in the "vacuum" treatment of air naturally occurring in the juice assure maximum retention of the natural vitamin content.

*Claims of Manufacturer.*—This tomato juice is a good source of vitamins A and B and an excellent source of vitamin C; for infant feeding and general table use.

## HELMS OLYMPIC WHITE BREAD AND HELMS HOME LIKE BREAD

*Manufacturer.*—Helms Bakeries, Ltd., Los Angeles.

*Description.*—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, page 817); prepared from patent flour, water, yeast, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, sweetened condensed skim milk, salt, lard, sucrose, invert sugar and tartaric acid.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture (entire loaf) | 34.2 |
| Ash | 1.9 |
| Fat (Polenske-Grujic method, Leach "Food Inspection and Analysis," ed. 4, p. 343) | 2.4 |
| Protein (N. × 6.25) | 9.5 |
| Crude fiber | 0.2 |
| Carbohydrates other than crude fiber (by difference) | 51.8 |

*Calories.*—2.7 per gram; 77 per ounce.

*Claims of Manufacturer.*—A bread of good quality.

## SMACO (204) CONCENTRATED LIQUID HALF-SKIMMED MILK (STERILIZED)

*Manufacturer.*—S. M. A. Corporation, Cleveland.

*Description.*—Evaporated half-skimmed milk containing half as much milk fat as ordinary evaporated milk.

*Manufacture.*—See this section for SMACO (203) Concentrated Liquid Whole Milk (Sterilized) (THE JOURNAL, July 25, 1931, p. 248); half-skimmed milk is used instead of whole milk.

*Analysis* (submitted by manufacturer).—

| | per cent |
|---|---|
| Moisture | 77.2 |
| Total solids | 22.8 |
| Ash | 1.5 |
| Fat | 4.0 |
| Prote | 6.9 |
| Lactose (by difference) | 10.0 |
| pH | 6.4 |

*Calories.*—1.0 per gram; 28 per ounce.

*Micro-Organisms.*—See this section for SMACO (203) Concentrated Liquid Whole Milk (Sterilized).

*Claims of Manufacturer.*—This product is intended especially for infant feeding for use wherever an evaporated partially skimmed milk is indicated.

## PORTAGE BRAND GOLDEN CORN SYRUP

(85 per cent corn syrup, 15 per cent refiners' syrup)

*Packer.*—D. B. Scully Syrup Company, Chicago.

*Distributor.*—Portage Wholesale Company, Portage, Wis.

*Description.*—A table syrup; a corn syrup base (85 per cent) with refiners' syrup (15 per cent).

*Manufacture, Analysis, Calories and Claims of Manufacturer.*—See these sections for Banner Blue Golden Syrup with Cane Flavor (THE JOURNAL, March 5, 1932, p. 817).

## EARLY STAGES OF VITAMIN A DEFICIENCY

Early in the study of the effects of a lack of vitamin A in the diet, several striking and serious symptoms of this form of avitaminosis were brought to notice. The decline in weight, in the case of growing animals deprived entirely of this vitamin, established the belief that it is essential to nutritive welfare. When Osborne and Mendel, in 1913, described eye disease, now identified as xerophthalmia, as a frequent consequence of deprivation of vitamin A, and McCollum, in 1917, called attention to respiratory disturbances under the same conditions of an inadequate dietary regimen, the consideration of the possibility that shortage of vitamin A in the diet is of serious moment in human well being rapidly began to develop. Meanwhile the pathology of experimental avitaminosis, related to lack of vitamin A, began to be elucidated further. The keratinization of certain tissues was noted, culminating in the extensive observations of Wolbach and Howe at Harvard University showing widespread metaplasia of the cylindric, cuboidal or transitional type of epithelium to the squamous, keratinizing type. This is not due merely to inanition, which may bring about atrophy of tissues but not metaplasia. Infection has also been injected into the pathologic picture by several of the investigators. Furthermore, when there is vitamin A shortage in the diet of laboratory animals there are alterations in the desquamative changes in the vaginal epithelium so characteristic of the estrual rhythm.

It seems to be generally agreed that by the time the body's reserves of vitamin A have been depleted and growth ceases in the young, the experimental animals become more susceptible to bacterial infection. It is not easy, however, to demonstrate cogently in what way, if any, there is an actual lowering of resistance to the effects of micro-organisms. At a stage when the protective epitheliums are no longer normal, it is readily conceivable that the exposed defective membranes may fail to offer the usual protection against bacterial invasion. Some students of the subject have suggested that there may also be a humoral protective effect attributable to adequate provision of vitamin A. On such grounds, some writers have ventured without hesitation to describe vitamin A as an antiinfective agent. It would be of great importance if there were convincing evidence of such a property. Unfortunately, our knowledge of avitaminosis is still largely limited to observations on laboratory animals, although extreme situations, such as are represented by xerophthalmia, are gradually being discovered in the study of human disorders. For the moment, some of the most critical reviewers have restricted their enthusiasms to the tentative somewhat indefinite conclusion "that vitamin A is an even more important factor in the chemistry of food and nutrition than has previously been appreciated, for it must be supplied in liberal proportion not only during growth but in the food of the adult as well, if a good condition of nutrition and a high degree of health and vigor are to be maintained."[1]

Among the difficulties encountered is the circumstance that the incipient stages of avitaminosis are not at all well defined. McLester[2] has recently asserted that the interest which vitamins hold for the physician is not alone in their relation to certain well defined diseases such as scurvy, beriberi and rickets but rather in the fact that chronic vitamin deficiency produces numerous vague, borderline states of ill health which often puzzle the physician and disable the patient. These last are of far greater importance to the physician of today than the more clearly defined deficiency diseases. From this standpoint there is added interest in studies by Thatcher and Sure[3] at the University of Arkansas. They have become interested in the early stages and the incipient signs of vitamin A deficiency. Their animal experiments lead them to conclude that pathologic changes may take place in tissues before any definite signs of external symptoms are apparent. For example, metaplastic changes in the posterior part of the tongue, in the salivary glands, and in the respiratory and urinary tracts were found during early stages of vitamin A deficiency in a large proportion of animals that made normal growth, some of which showed incipient ophthalmia or persistence of the cornified stage of estrus as the only sign of vitamin A deficiency, and others of which showed no external signs of A avitaminosis. Bronchitis and pneumonia were also found in several animals that still made slight gains in weight before the termination of the experiment. Thatcher and Sure therefore suggest that metaplasia of epithelial structures in the respiratory tract of man possibly begins before definite external symptoms are evident, which later may be responsible for the respiratory disturbances, such as are found associated with the A avitaminosis—the common cold, bronchitis and bronchopneumonia. This is, let it be vigorously emphasized, a tentative hypothesis. It does not warrant the exploitation of common dietary sources or concentrates of vitamins as cures of colds or influenza; but these experiments represent a step in the direction of progress in elucidating what resistance and immunity may involve.

## THE ALLEGED DISTRIBUTION OF INSULIN

Not long after the discovery of insulin was announced, a widespread search was begun in many laboratories to ascertain the possible distribution of this potent and remarkable hormone of the pancreas. The upshot of these investigations was the publication of numerous claims of the rather widespread distribution of substances having insulin-like action. They were reported not only for animal tissues but also for plant products of varied sorts, ranging from oatmeal to onions. These records naturally led to an intensive search for easily obtainable substitutes for pancreatic insulin, since the preparation of the latter offered difficulties and involved considerable expense. The testing of insulin calls at present for experiments on animals; in comparison with many familiar chemical test reactions, it is a more laborious and less specific procedure. The current method depends primarily on the effects of insulin in producing a prompt hypoglycemia and, if the dose is adequate, characteristic hypoglycemic convulsions. It should be noted that the reports of the insulin-like products from plant tissues indicate some difference from the insulin of animal sources in that the action of the plant substances in lowering the content of blood sugar is often not immediate but delayed for a considerable period—sometimes twelve hours or more. The occasional reports of the presence of insulin in tissues of diabetic patients have been particularly confusing.

One difficulty in all investigations in this field lies in the intricacy of the extraction methods. In summarizing the confusing situation, competent critics[1] have pointed to a number of reasons why the results of the early work on the distribution of insulin and insulin-like substances are of no significance from the quantitative point of view. It was not then fully appreciated that some test animals may show a definite fall in blood sugar over the experimental period, and for this reason the results based on one animal are not satisfactory. A standard of comparison was not used in the assaying of insulin in most of the early work. In a number of the later papers that have appeared on the subject of the distribution of insulin, convincing evidence is not found that any hypoglycemia-producing substance was present in the extracts which were reported to yield positive results. When we add to these factors the possibility of the presence of a living agent which may cause hypoglycemia, the possibility that nonspecific toxic materials, which may produce liver damage and delayed hypoglycemia, may have been present, and the possibility of contamination of solutions by pancreatic insulin, it becomes apparent, the critics conclude, that the whole question of the distribution of insulin and insulin-like substances must be reopened, and that many if not all of the results obtained up to now, discarded.

Such a reinvestigation has been undertaken by one of the discoverers of insulin, Dr. C. H. Best, and his co-workers[1] at the University of Toronto. The intricate details need not be rehearsed here. Using a method of extraction which yields maximal amounts of insulin from pancreas, the Toronto physiologists have been unable to demonstrate the presence of an antidiabetic substance in other normal tissues from the dog or ox or in the tissues of diabetic dogs. After a critical appraisal of the evidence on record, Best and his associates believe that there is no evidence that any tissue other than pancreatic either produces or stores insulin.

## SLEEP AND THE BRAIN CORTEX

In an exhaustive review of sleep, a subject that concerns the physician as well as the layman in many ways, Kleitman[1] of the University of Chicago remarked that the problem has yet to be solved. There is no authority but that of facts, and until isolated observations have been repeatedly confirmed they cannot be classed as established facts. We are so commonly accustomed to think of sleep as part of the physiology of the brain that we may fail to consider to what extent other parts of the body or their functions may be responsible for, or involved in, the more or less complete unconsciousness under discussion. Is the cerebral cortex an essential factor in sleep? In attempting to answer this important query, physiologists have been reminded of the published records indicating that decorticated animals can sleep. This was true, for example, in the classic observations of Goltz in 1892. He reported that dogs deprived of their cerebral cortex exhibited phenomena of sleep.

In this connection the distinctions that have been stressed by Szymanski[2] in interpreting the phenomena of unconsciousness may be recalled. He demonstrated conclusively that some animals have one long period of rest in twenty-four hours and that others have several such periods. He termed them monophasic and polyphasic animals. The polyphasic are the "lower" animals, which make little use of their distance receptors for obtaining information about what is going on around them. Szymanski points out, however, that even among the monophasic animals, including man, the young are polyphasic. In the case of adult man, interest centers in the monophasic manifestation often referred to as diurnal sleep, represented by the characteristic prolonged periods of unconsciousness and comparative inactivity. Dogs exhibit the same phenomena.

---

[2] Szymanski: Arch. f. d. ges. Physiol. **171**: 324, **172**: 424, 430, 1918; Ztschr. f. allg. Physiol. **18**: 105, 1920.

In a reinvestigation of the possible existence and localization of a sleep center, Kleitman and Camille[3] of the University of Chicago Department of Physiology have observed that decorticated dogs have several periods of sleep alternating with periods of activity each twenty-four hours. Their activity consists of almost incessant walking in circles. The most constantly occurring period of sleep follows shortly on feeding. The conclusion is made that diurnal sleep in dogs depends on the presence of the cerebral cortex for its establishment and persistence. In other words, normal dogs can stay up all day and then sleep through the night, whereas decorticated dogs have half a dozen periods of sleep in twenty-four hours.

The Chicago physiologists accordingly believe that there is no conflict between the subcortical and the cortical theories of sleep. The first account for sleep in general, the second for the special diurnal type of sleep seen only in higher animals and in man. As Kleitman and Camille point out, diurnal sleep, developed around the twenty-four hour cycle of day and night, is thus a definitely cortical phenomenon, has its center or is localized in the cerebral cortex, and disappears when the cortex is removed. That explains, they add, why all those who study the sleep of higher animals and man cannot help but see the tremendous influence of cortical processes, habits and conditioned reflexes on the onset of sleep. In man the habit of going to bed at certain hours, and of waking up at a definite time each morning, is not inborn but acquired by experience. That the subcortical sleep tendencies are ever ready to exert their action is demonstrated by the fact that most people can fall asleep not only at their habitual bedtime but at almost any time, if a condition is brought about wherein the number of afferent impulses reaching the cerebral cortex is greatly reduced. After a meal the primordial tendency to sleep is especially powerful and asserts itself with great ease, if permitted to do so. As Kleitman has elsewhere pointed out, practically we are born into a social organization in which diurnal sleep is the universally accepted mode of sleeping. The new-born baby is a truly polyphasic creature, to use Szymanski's classification. The first habit the mother tries to develop in a baby is that of an unbroken night's sleep. As he gets older, other functions develop a periodicity that coincides with the enforced sleep periodicity. For instance, a temperature curve develops, with a minimum at night, and produces a disinclination to night activity. Even the modest tear apparatus stops its function at bedtime, producing dry eyes and favoring their closure. Attempts to influence or induce sleep may well be based on some of the fundamental facts now on record.

### INCREASING RATES OF GROWTH

The rapid development of the science of nutrition during the past three decades has been due, in no small measure, to the ready adaptability of the white rat to the experimental conditions required in investigations in this field. The details of its reproduction and life history, the physical measurements of the organs and systems, the rate of development and the nutritive requirements of this animal, have been studied intensively; the completeness of the pertinent data render the white rat a surprisingly well standardized piece of "apparatus" available for studies in nutrition. It has been observed during the past twenty-five years that the rate of growth of the species has increased considerably. Whereas the average weight of males at 100 days of age was 165 Gm. in 1906, the value for a large number of individuals of the same sex and age was 315 Gm. in 1928. An account of the most rapid rate of growth thus far observed in this species has recently been reported by Anderson and Smith.[1] With a group of twenty-one animals the average time required for increase in body weight from 60 to 200 Gm. was 23.3 days and from 60 to 300 Gm. 41.1 days. It is emphasized by the Yale investigators that there is nothing unique about their animals from the point of view of heredity but that the rapid growth was brought about by providing a favorable diet. The food given was a mixed ration containing liberal allowances of protein, vitamins and inorganic salts. These studies indicate that thus far the growth-limiting factor in the development of the laboratory white rat has been the nutritive environment rather than the growth impulse that is presumably characteristic of the species. The animals that have shown this extremely rapid growth are not abnormal; this is indicated by previous studies[2] in which it was shown that mature individuals of the same size have identical body measurements and proportions, regardless of the rate at which they grew. That this phenomenon of increasing rate of growth is being observed in certain groups of human subjects is evident from the literature on the subject during the past twenty-five years. One of the most striking accounts of increased size is that of Gray,[3] who described a group of private school boys which showed a rate of growth consistently greater than is found in the average individual of the same age. It would appear possible, therefore, to accelerate still further the rate of development in certain species. The question as to whether or not maximum growth is also optimal has been raised by Smith,[4] who points out that "the law of diminishing returns undoubtedly is operative in animal and plant economy, as well as elsewhere." Certainly the study of geology and of biology emphasizes the futility of mere great size. However, it cannot be disputed that the race has been greatly benefited by the application of just such nutritive principles as have first been shown to be of advantage in the development of experimental animals.

# Association News

## MEDICAL BROADCAST FOR THE WEEK

### American Medical Association Health Talks

The American Medical Association broadcasts on Monday and Wednesday from 1:30 to 1:35 p. m. over Station WBBM (770 kilocycles, or 389.4 meters). The Columbia chain program has been discontinued for the present.

The program for the week is as follows:

June 27. Hot Weather.
June 29. Independence Day Indiscretions.

There is also a fifteen minute talk sponsored by the Association on Saturday morning from 11:15 to 11:30 over Station WBBM.

The program for the week is as follows:

July 2. July Fourth Follies.

This schedule is based on Chicago Daylight Saving Time, one hour faster than Central Standard Time, and is subject to change during the summer.

---

# Medical News

(Physicians will confer a favor by sending for this department items of news of more or less general interest: such as relate to society activities, new hospitals, education, public health, etc.)

## COLORADO

**Society News.**—The Crowley County Medical Society was addressed in Ordway, May 10, by Dr. Earnest O. McCleary on "Puerperal Eclampsia." Dr. William M. Desmond reported a case of "Carcinoma of the Tongue."——At the meeting of the Las Animas County Medical Society, May 6, Dr. Walter L. Newburn, Trinidad, read a paper on "Cholecystitis and Cholelithiasis."——Dr. Johnson E. Naugle addressed the Northeast Colorado Medical Society in Sterling, April 14, on "The Böhler Treatment of Fractures." The society was addressed, May 12, by Drs. John S. Chase, Jr., and Arnold Minnig, Denver, on "Diagnosis and Treatment of Squint" and "Nonsurgical Treatment of Goiter," respectively.——"Spinal Anesthesia" was the topic discussed by Dr. George E. Rice, Pueblo, before the Otero County Medical Society, April 14.——The Pueblo County Medical Society was addressed, May 17, by Drs. Clarence E. Earnest and Harvey S. Rusk on sinus disease.

## CONNECTICUT

**Hospital News.**—The Arnold Pavilion for Children at St. Luke's Convalescent Hospital, Greenwich, was dedicated, May 21. The pavilion is two stories high and will provide for about fifty children. It was the gift of Mrs. Harriet M. Arnold, in memory of her husband, Hicks Arnold.

**New Health Officers.** — Connecticut *Health Bulletin* announces the following recent changes among health officers: Dr. John R. Tarrant as health officer of Portland, succeeding Dr. Donald J. MacGillivray; Dr. Theodore F. Foster, health officer of West Hartford, and James J. Charron, health officer of Putnam. West Hartford recently voted to operate its health department on a full time basis.

**Regulation for Bathing Establishments.** — The Public Health Council, state department of health, at its meeting, April 21, approved the adoption of a new sanitary code regulation for bathing establishments, effective June 1. The regulation will govern management of the grounds and appurtenances of any bathing establishment on or near any stream, natural or artificial pond, or tidal water where bath houses for the use of the public are maintained either free or for hire.

**Memorial Pavilion Opened.**—The Sarah Wey Tompkins Memorial Pavilion, with 139 beds for surgical and obstetric patients, was officially opened, June 18, at the New Haven Hospital. Funds for the pavilion were provided in a bequest to Yale University, by Mrs. Sarah Wey Tompkins, whose father, Dr. William C. Wey, practiced for half a century in Elmira, N. Y. Completion of the memorial increases the capacity of New Haven Hospital to 514 beds and 42 bassinets. The new six-story wing conforms in style to the architecture of the other buildings. Half of the beds are in single rooms, and the largest ward has eight beds. With the completion of the Tompkins Memorial, all of the outpatient and inpatient service of the New Haven Hospital will be concentrated in the same set of buildings adjoining the Yale University School of Medicine. In the gradual replacement of old buildings at the New Haven Hospital, the completed structures have cost more than $4,000,000.

## DISTRICT OF COLUMBIA

**Personal.**—Capt. William H. Bell, medical officer in command of the Naval Medical School, Washington, D. C., was an official delegate to the second session of lectures of the International Bureau of Documentation on Military Medicine, Liége, Belgium, June 23-25.——Dr. Arthur C. Christie, Washington, past president of the Medical Society of the District of Columbia, was elected president of the Washington Rotary Club at its annual meeting, May 25.

**District Bills in Congress.**—S. 1307 has been reported to the House, without amendment, authorizing an appropriation for the alteration and repair of the buildings of Eastern Dispensary and Casualty Hospital. H. R. 11638 has been passed by the House, amending the license fees law of the District of Columbia. Paragraph 8 of the bill provides: "Apothecaries or druggists shall pay a license fee of $12 per annum. Every person who sells patent medicines, or manufactures, compounds, sells or dispenses medicines by prescription or otherwise from a located place of business shall be regarded as an apothecary or druggist."

**Honorary Degrees Conferred.**—The honorary degree of doctor of science was conferred by George Washington University on Dr. Frederick Parker Gay, professor of bacteriology, Columbia University College of Physicians and Surgeons, June 15, at the commencement exercises. Similar degrees were conferred on Dr. G. Canby Robinson, dean, New York-Cornell Medical Center, and Dr. Alan Mason Chesney, dean and associate professor of medicine, Johns Hopkins University School of Medicine. Because of the emphasis which the university has placed on the further upbuilding of its school of medicine in the past year, the commencement exercises centered about medical education. Dr. Gay delivered the commencement address, on "Significance of Science in Medicine."

## ILLINOIS

**Typhoid Fever in Springfield.**—Four typhoid carriers were detected recently, when the development of sixteen cases of typhoid in Springfield led to a search for carriers among milk handlers and certain food handlers of the city. Two of the carriers were employed by the same milk dealer, one being a butter wrapper and the other an ice cream dispenser. Another made ice cream, which he sold from his own stand, while the fourth carrier delivered milk from a wagon. The state health department believes that the discovery of these carriers solves the outbreak, as no new cases have developed.

### Chicago

**Society News.**—Dr. Austin A. Hayden became president-elect of the Chicago Medical Society at a meeting, June 14, and Dr. Charles H. Phifer was reelected secretary. At the annual dinner, June 15, Dr. Herman L. Kretschmer was installed as president of the society, succeeding Dr. John R. Harger.

**Personal.**—The Cross of a Chevalier of the Order of the Crown of Italy was conferred on Dr. Louis D. Moorhead, dean and professor of surgery, Loyola University School of Medicine, June 13. The decoration was conferred by Giuseppe Castruccio, Italian consul general in Chicago.——Dr. Earl B. Ritchie has resigned as assistant professor of dermatology at the Graduate School of Medicine of the Division of Biological Sciences, University of Chicago.

**The Annual Rush Banquet.**—Seven members of the class of 1882 were guests of honor at the annual alumni banquet of Rush Medical College, June 14. They were Drs. Malcolm L. Harris, Chicago, Past President, American Medical Association; John M. Dodson, formerly Director, Bureau of Public Health and Instruction, American Medical Association; Frederick G. Stueber, Lima, Ohio; John C. Wright, Antigo, Wis.; Elmore S. Pettyjohn, Chicago; Zalmon E. Funk, Santa Rosa, N. M., and John P. Lord, professor of orthopedic surgery, University of Nebraska College of Medicine, Omaha. Replies were received from nineteen other members of the class who were unable to attend. Of the 181 members of the class of 1882, 49 are known to be living; 85 are dead, and the remainder are at addresses unknown. Dr. Dodson gave the Alumni Memorial Address, on "Delaskie Miller." This was a eulogy of Dr. Miller, who was professor of obstetrics at Rush from 1859 to 1899. He was also a member of the board of trustees. He established the Delaskie Miller Prize, consisting of a fitted obstetric bag, which is awarded to the student doing the best work in obstetrics and gynecology. The toastmaster at the banquet was Dr. Clifford G. Grulee. Dr. Edwin M. Miller, class of 1913, president of the association, spoke. Responses were given by Drs. Morris Fishbein, class of 1912, editor of THE JOURNAL, and Donald R. Laing, class of 1932. Speakers for Rush and for the University of Chicago were Dr. Ernest E. Irons, dean, Rush Medical College, and Frank R. Lillie, Sc.D., dean of the Division of the Biological Sciences of the university. Dr. Charles A. Parker, class of 1891, was elected president of the alumni association.

## INDIANA

**Society News.**—Dr. Charles Kenneth Riddle, Cincinnati, addressed the Dearborn-Ohio County Medical Society, May 26, in Lawrenceburg, on diabetes.——At the May 25 meeting of the Ripley-Decatur County Medical Society in Osgood, Dr. Vincent A. La Penta, Indianapolis, spoke on "Gastric and Duodenal Ulcer."——"Skull Fracture and Brain Injuries" was the subject discussed by Drs. Jewett V. Reed and Charles F. Thompson, Indianapolis, before the Lawrence County Medical Society, Bedford, May 4.

**Well Baby Clinic.**—An anonymous gift of $5,500 to provide for the establishment of a well baby clinic at the University of Indiana School of Medicine, Indianapolis, was announced in newspapers, June 1. The clinic, which will be equipped and maintained at the Coleman Hospital for three years through this gift, will be connected with the department of pediatrics, of which Dr. Matthew Winters is the head. It will be open on Wednesday of each week for the examination of babies and will be available to mothers unable to pay. The purposes of the clinic are to instruct the medical school students in the care and development of normal children and to educate mothers in the care and feeding of infants. Dr. Lyman T. Meiks will be in direct charge.

## IOWA

**Summer Round-Up Clinics.**—Immunization against diphtheria was the theme during the summer round-up of preschool children at fifteen centers, conducted by the Des Moines Parent-Teachers Association. The first injection of diphtheria toxoid was offered at each clinic with the announcement that the second dose might be obtained from the family physician or from the city health officer at a specified time. This activity is the first step in the program of a committee recently appointed by the president of the Polk County Medical Society, Dr. Simon E. Lincoln, Des Moines, to promote the plan for immunization of children against diphtheria. This committee is composed of Drs. Fred Moore, Addison C. Page and Harry E. Ransom. The second step in the immunization program will be the protection of babies in attendance at feeding clinics conducted by the Public Health Nursing Association. The bulletin of the Des Moines Academy of Medicine and the Polk County Medical Society states that diphtheria has been increasing in Polk County during the past two years.

## KANSAS

**Society News.**—The Sedgwick County Medical Society was addressed, May 17, by Dr. Ray A. West on "Biological Tests for Pregnancy—Review of Literature and Presentation of New Technic."——The Wyandotte County Medical Society was addressed, May 17, by Drs. Tony G. Dillon and Oscar W. Davidson on hematuria and pyuria, respectively.——The May issue of the bulletin of the Sedgwick County Medical Society is called the Dorsey Honor Number in memory of the late Dr. Jacob G. Dorsey.——The Decatur-Norton Counties Medical Society was addressed, April 14, by Drs. E. F. Steichen, Lenora, on "Use of Local Anesthesia in the Reduction of Fractures"; Frank Wayne Brewster, Oberlin, "Duodenal Stasis," and Jesse S. Potekin, Hoxie, "Arthritis." Dr. Brewster presented a film on "Infections of the Hand."——Dr. Clifford L. Hooper, Dodge City, addressed the Ford County Medical Society, April 8, on "State Medicine."

## MARYLAND

**Personal.**—Dr. William H. Welch, director emeritus of the Institute of the History of Medicine, Johns Hopkins University, Baltimore, received the honorary degree of doctor of science from New York University at its commencement, June 8.——Dr. Valcoulon L. Ellicott has been appointed deputy state health officer and full time health officer of Montgomery County, succeeding the late Dr. William T. Pratt, Rockville, effective April 15.

**Investigation of Food Poisoning.**—The Baltimore City Health Department recently organized a "team" to investigate cases of food poisoning. R. S. Craig, director, bureau of chemistry and food, is in charge of this group. Others on the "team" are Ferdinand A. Korf, assistant director of the bureau of chemistry and food and in charge of the food division; Dr. Ferdinand O. W. Reinhard, director, bureau of communicable diseases; Dr. William H. F. Warthen, director, bureau of child hygiene; Leroy Ewing, director, bureau of bacteriology, and H. R. Broll, chief of the division of chemistry.

**Change in Service at City Hospitals.**—Twenty-four hour service for the admission in the hospitals of acutely ill patients, obstetric patients and persons suffering from tuberculosis and venereal diseases will be installed in Baltimore City hospitals as soon as practicable, in accordance with the recent action of the board of supervisors of city charities, which has charge of the hospitals. Under this plan the health department will deal directly with the hospitals when seeking to have a patie admitted, instead of through the supervisors of the city char ties. Requests from the department for hospitalization fo tuberculous, maternity or venereal disease cases will be give priority over other cases, so far as there may be vacant and available beds at the city hospitals. It is also planned to install, as soon as possible, thirty beds for the hospitalization of patients with acute venereal diseases. Under the new arrangement, the city department of health will continue its obstetric delivery service until October, 1933, when the work will be taken over by the staff of the hospitals. These changes, which have been approved by the board of supervisors, were recommended, May 20, at a conference held by the president of the charities board, the city director of health and the superintendent of the hospitals. It is expected that the Baltimore City hospitals and the department of health will thus be brought into closer cooperation.

## MASSACHUSETTS

**Hospital News.**—The new Winthrop Hospital, Winthrop, was to have been opened for patients about March 1. It has a bed capacity of fifty, an increase of twenty-six over the old institution housed in wooden frame buildings.

**Society News.**—Dr. William E. Browne, Boston, was elected president of the Massachusetts Society of Examining Physicians at its annual meeting, April 27, in Boston, and Dr. William Pearce Coues, secretary. The speakers at this meeting included Drs. George V. Foster, Pittsbugh, on "Treatment of Compound Fractures," and Henry C. Marble, "Volkmann's Contracture."——The New England Heart Association conducted a cardiac course on "Chronic Myocarditis," June 1; the participating physicians were Drs. Shields Warren, Henry A. Christian, Henry Jackson and Francis W. Palfrey.——At the annual meeting of the Worcester District Medical Society, May 11, Dr. Edwin R. Leib, Worcester, was elected president. Dr. Walter C. Seelye, Worcester, gave the annual oration, on "Congenital Pyloric Stenosis."

## MICHIGAN

**Home for Incurable Cancer Patients.**—Mercy Hall, a free home in Detroit for incurable cancer patients too poor to pay for treatment, is now located in the thirty-room residence of the late Judge G. S. Hosmer, which has been given rent free by Miss Dorothy Brown. Opened for the first time in October, 1931 (THE JOURNAL, Nov. 14, 1931, p. 1473), Mercy Hall has cared for thirty-one cancer patients, has given five operations, and has taken charge of the burial of one patient. At present its eleven beds are occupied. The institution is operated by the Society of Perpetual Help, a group of five Detroit women, with no remuneration. It is one of three organized for the same purpose in the United States, it is reported. Dr. Louis J. Morand is president of the corporation and head of the medical staff. Mercy Hall was open to public inspection, June 5. Previously it occupied quarters in a twelve-room house at 312 Watson Street. It is understood that Detroit physicians have volunteered their services to this enterprise, through the Commission for Cancer Control of the Detroit Board of Health and the corresponding committee of the Wayne County Medical Society.

## MINNESOTA

**Dr. Buie Awarded Medal.**—The Southern Minnesota Medical Society presented its gold medal to Dr. Louis Arthur Buie, associate professor of proctology, University of Minnesota, Graduate School of Medicine, Rochester, May 25, for research in the treatment of intestinal disorders. The medal, which is awarded annually, was presented at the closing session of the Minnesota State Medical Association.

**Schuster Tries Another State.**—George Schuster pleaded guilty, May 9, to practicing healing without a basic science certificate in Minneapolis and was fined $100. He paid the fine. The state board reported that Schuster admitted that he had been convicted twice previously of practicing medicine without a license: in 1921 at Youngstown, Ohio, and, in 1928, at Chicago. His illegal practice of healing in Minnesota became known following his complaint in Chicago that one William W. Blyth swindled him out of $2,050 for a fake medical license. Schuster claimed to have been ordained a German Lutheran minister in 1909 at Pittsburgh. He also claimed to be a member of a naturopathic association.

## NEBRASKA

**Society News.**—Dr. Arthur D. Dunn, Omaha, addressed the May meeting of the Madison Six-County Medical Society, West Point, on "Relationship of Paranasal Sinusitis to Systemic Disease."——Drs. Adolph Sachs, Omaha, and Floyd S. Clarke addressed the Otoe County Professional Society, Nebraska City, May 9, on agranulocytosis and pneumonia in children, respectively.——At a meeting of the Cheyenne-Kimball-Deuel Counties Medical Society, Chappel, May 2, Drs. Charles F. Heider and Edward Stevenson, North Platte, spoke on "Diagnostic Problems in Kidney Lesions" and "Cerebrospinal Meningitis in Children," respectively.

**Dr. Long Honored.**—Dr. Francis A. Long, Madison, editor of the *Nebraska State Medical Journal*, was guest of honor at a dinner given by the Madison Six-County Medical Society, April 15, in Norfolk, commemorating his fiftieth year in medical practice. Dr. Benjamin F. Bailey, Lincoln, was toastmaster and the speakers were Drs. John E. Summers, John P. Lord, Albert F. Tyler and Byron B. Davis, all of Omaha; Roy B. Adams, Lincoln, and Morris Nielsen, Blair. A fountain pen desk set was presented to Dr. Long. A native of Pennsylvania, Dr. Long moved west with his parents when he was 18 years old and was graduated from the Medical Department of the University of Iowa in 1882, settling in Madison shortly afterward. Dr. Long was one of the founders of the Elkhorn Valley Medical Society and served as its third president. In 1906-1907 he was president of the Nebraska State Medical Association. He first advocated the creation of a state journal. He has served continuously since 1916 as chairman of the publication board and has been editor since 1920.

## NEW JERSEY

**Annual Clinics.**—The staff of Hackensack Hospital, Hackensack, presented its third annual program of clinics for physicians, May 23-27. Demonstrations were held in pediatrics, fractures and orthopedics, otolaryngology, obstetrics, gynecology, medicine, surgery, dentistry and laboratory methods. Dr. Harrison B. Wilson was chairman of the demonstration committee, which included also Drs. Howard M. Meyer and Spencer T. Snedecor and Miss Mary Stone Conklin, superintendent of the hospital.

## NEW YORK

**Study of Health Habits.**—A state-wide study of the health habits of 3,500 school children has been made during the current school year under the supervision of the health and physical education division of the state education department for the purpose of obtaining information to be used as a basis for a new state guide in health teaching for the kindergarten and first six grades. The department prepared a check list of 600 questions covering all phases of health behavior of children in and out of school. Seventeen hundred teachers in fifty-four communities were asked to select two children for observation during school hours for six weeks. The study was then carried into the homes in order to have a twenty-four hour record of the children's health habits. The entire study was to be made without the children's knowledge. The data for about 3,500 children have now been turned in to the state department for analysis, after which the returns will be used in setting up objectives for health education.

**Society News.**—Dr. George M. MacKenzie, Cooperstown, was elected president of the New York State Association of Public Health Laboratories at the annual session, May 23.——Drs. Thomas I. Tyrell and Harold P. McGan addressed the Medical Society of the County of Albany, June 10, on "Fractures of the Skull and Newer Methods of Treatment" and "Medical Aspects of Dysmenorrhea," respectively.——Dr. Charles H. Mayo, Rochester, Minn., addressed a joint meeting of the Broome County Medical Society, the Binghamton Academy of Medicine and the Binghamton Dental Society, in Binghamton, June 17, on infections with special reference to focal types and on elective localization and mutation of bacteria.——Drs. Thomas Ordway and Don Morse Griswold, both of Albany, addressed the Schoharie County Medical Society, Middleburg, May 2, on "Diagnosis and Treatment of Pneumonia" and "Medical Ethics," respectively.——Dr. Alvan L. Barach, New York, gave an address on the therapeutic use of oxygen in cardiorespiratory diseases before the Sullivan County Medical Society in Liberty, May 11.

### New York City

**Hospital News.**—The fortieth anniversary of the incorporation of the Jamaica Hospital was observed with a dinner dance, April 13, at the Waldorf-Astoria Hotel.——Irvington House, a convalescent home for children with heart disease, with a capacity of 150 beds, was dedicated, May 25, at Irvington-on-Hudson. It is said to be the fifth convalescent home in the metropolitan area.——The marine roof on the new wing of the New York Postgraduate Medical School and Hospital was opened, May 26.——A clinic for the treatment of children injured at birth has been opened at the Neurological Institute, Columbia University Medical Center, under the direction of Dr. Earl R. Carlson.

**New Hospital.**—The new nine-story building of the Bronx Hospital, completed in 1930 and unoccupied since that time because of financial difficulties, was opened, June 12. The building, which has a capacity of 310 beds, represents an investment of $2,500,000. One floor is devoted to private rooms, another to semiprivate rooms and one to rooms for children. There are no large wards, but ward patients are cared for in small units, their beds separated by curtains. The hospital has five operating rooms, five laboratories and a research laboratory for general investigative work. The old hospital building, directly across Fulton Street, will be used as a dispensary.

**Prizes to Medical Graduates.**—Two members of the graduating class and one graduate of 1920 were awarded prizes for meritorious work in medicine at the annual commencement of Columbia University College of Physicians and Surgeons. Robert Lloyd Windsor won the Thomas F. Cock Prize, the annual income from a fund of $1,000, for a thesis on puerperal fever. Henry Scott Waters was awarded the Dr. William Perry Watson Prize in Pediatrics, the annual income from a fund of $5,000, for notable work in the study of diseases of infants and children. Dr. Raphael Kurzrok, a 1920 graduate of Columbia, was awarded the Joseph Mather Smith Prize, the annual income from a fund of $3,500, for achievements in the application of biochemistry to the problems of sterility.

## NORTH CAROLINA

**University News.**—Dr. Ralph Pemberton, Philadelphia, gave a clinic on arthritis at the Duke Hospital of Duke University School of Medicine, Durham, April 8. A clinic on cancer was conducted at the hospital, April 15, by Dr. Warren H. Lewis, Carnegie Institution of Washington, Washington, D. C. Dr. Ernest W. Goodpasture, Nashville, Tenn., lectured at the hospital, April 22, on "Cytotropic Viruses."

## OHIO

**Personal.**—The University of Cincinnati at its fifty-fourth annual commencement, June 11, conferred the honorary degree of doctor of laws on Dr. George J. Heuer, who recently resigned as Holmes professor of surgery in the college of medicine to become surgeon-in-chief of the New York Hospital and professor of surgery at Cornell University School of Medicine, New York (The Journal, Feb. 21, 1931, p. 621). Dr.

Johnson McGuire, instructor in the college of medicine, has been appointed assistant professor of medicine, effective July 1. ——Dr. Morris C. Tarr, who has practiced medicine fifty years in Wellsville, was the guest of honor at a banquet sponsored by the Kiwanis Club of Wellsville, May 12. A gold watch was given to Dr. Tarr.

## PENNSYLVANIA

**Society News.**—Drs. Herbert G. Wertheimer and Andrew P. D'Zmura, among others, addressed the Allegheny County Medical Society, Pittsburgh, at the final meeting of the season, June 21, on treatment of erysipelas and the clinical value of electrocardiography, respectively.

**Five Chiropractors Convicted.**—Five chiropractors of Harrisburg were convicted in the Dauphin County Court, June 2, of practicing medicine without a license. Fines were imposed and all were placed on probation for three years. Robert W. White was fined $250 and costs and the remaining four were fined $100 each after pleading nolle contendere. The latter were W. Ray Burns, Howard A. Von Neida, O. D. Shankland and Henry Wohlgemuth. Hon. Robert R. Lewis, Coudersport, was the presiding judge.

### Philadelphia

**University News.**—Dr. John M. T. Finney, Baltimore, delivered the commencement address at the Woman's Medical College of Pennsylvania, June 8. Dr. Elise S. L'Esperance, New York, addressed the alumnae association, June 7, on "The Relation of Tuberculosis to Hodgkin's Disease." Dr. Catharine MacFarlane, Philadelphia, became president of the association and Dr. Mary Bickings Thornton, Philadelphia, president-elect.

**Society News.**—Drs. Frederic Maurice McPhedran, Philadelphia, and James J. Reilly, Camden, N. J., among others, addressed the Philadelphia Pediatric Society, June 14, on "Artificial Pneumothorax in the Childhood Types of Tuberculosis" and "Still's Disease," respectively.——Dr. Walter S. Cornell, medical director of the Philadelphia public schools, has been chosen president-elect of the Philadelphia County Medical Society. Dr. Charles F. Nassau now is the president.

**Personal.**—The honorary degree of doctor of laws was conferred on Dr. William N. Parkinson, dean of Temple University School of Medicine, at the annual commencement of Villanova College, Villanova, Pa.——Dr. Paul J. Pontius received the honorary degree of doctor of science at the commencement exercises of Bucknell College, Lewisburg, Pa., June 6.—The honorary degree of doctor of laws was conferred on Dr. William Wayne Babcock at the commencement exercises of Temple University.——Dr. Samuel Horton Brown has been appointed a member of the State Council for the Blind by Governor Pinchot.

## RHODE ISLAND

**State Medical Election.**—Dr. Charles S. Christie, West Warwick, was named president-elect of the Rhode Island Medical Society at the annual meeting, June 2, and Dr. Norman D. Harvey, Providence, became president. Dr. James W. Leech, Providence, was reelected secretary.

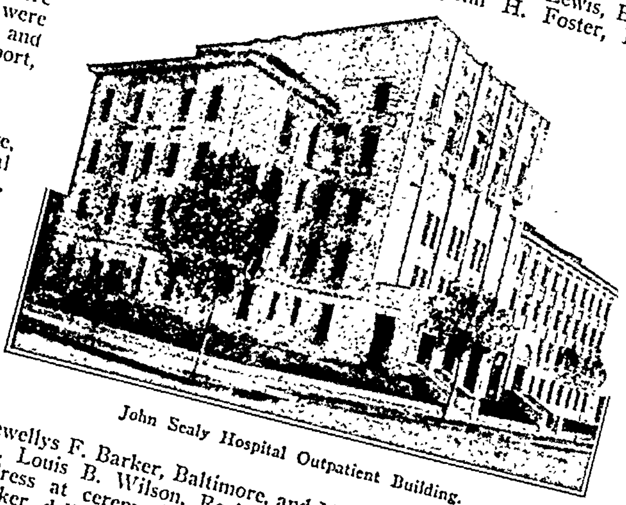
## TENNESSEE

**Society News.**—Drs. Virgil E. Simpson, Louisville, Ky., and Milton A. Gilmore, Hopkinsville, Ky., addressed the Montgomery County Medical Society, Clarksville, at a meeting, May 18, at which physicians of Christian and Todd counties (Kentucky) were guests.——Dr. Oval N. Bryan, Nashville, was elected president of the Middle Tennessee Medical Association at a meeting in Sparta, May 5-6.——Dr. William Oscar Baird, Henderson, was elected president of the West Tennessee Medical and Surgical Association at the recent annual meeting in Jackson. Dr. Isaac A. McSwain, Paris, secretary for more than forty years, was reelected.

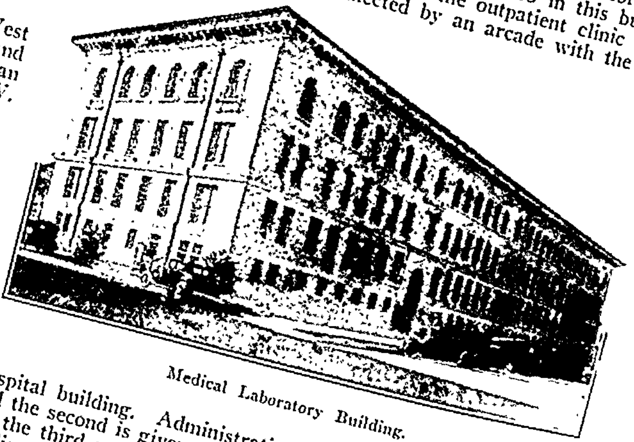
**Health at Memphis.**—Telegraphic reports to the U. S. Department of Commerce from eighty-five cities with a total population of 37 million, for the week ended June 11, indicate that the highest mortality rate (18.1) appears for Memphis and the rate for the group of cities as a whole, 10.8. The mortality rate for Memphis for the corresponding week last year was 13.3 and for the group of cities, 10.7. The annual rate for the eighty-five cities was 12.2 for the twenty-three weeks of 1932 as against a rate of 13.1 for the corresponding period of 1931. Caution should be used in the interpretation of weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have large Negro populations may tend to increase the death rate.

## TEXAS

**New Medical Buildings at the University.**—Three new buildings were dedicated at the University of Texas School of Medicine, Galveston, May 30-31, in connection with the annual graduating exercises. The buildings, which are a medical laboratory, the John Sealy Hospital Outpatient Building and the Rebecca Sealy Residence for Nurses, were erected by the board of regents of the university and the trustees of the Sealy and Smith Foundation at a cost of about $2,500,000. The first day was devoted to clinics and scientific addresses with the following guest lecturers, among others: Drs. Oscar H. Plant, Iowa City; Edward H. Cary, Dallas; Dean Lewis, Baltimore; Rudolph Matas, New Orleans; John H. Foster, Houston; Lewellys F. Barker, Baltimore, and Marvin L. Graves, Houston. Dr. Louis B. Wilson, Rochester, Minn., made the dedicatory address at ceremonies in the morning of May 31, and Dr. Barker delivered the commencement address in the evening. The new laboratory building has four floors. It contains laboratories for histology, embryology, pathology, anatomy and experimental surgery. In addition, there are a museum of surgical pathology of 2,000 specimens and a museum of general pathology of 3,000 exhibits. A library with space for 60,000 volumes and two large lecture halls are also in this building. The five-story building erected for the outpatient clinic of the John Sealy Hospital is connected by an arcade with the main hospital building. Administrative offices are on the first floor, and the second is given over to x-ray equipment and to surgery. On the third are laboratories for basal metabolism and electrocardiography and clinics for ophthalmology, otolaryngology, obstetrics and gynecology. Laboratories, amphitheaters and the mortuary room occupy the fourth floor, and the fifth is used for animal houses, supplies and storage of x-ray films. The nurses' residence has rooms for 165 nurses, an auditorium seating 250 persons and a number of classrooms.



John Sealy Hospital Outpatient Building.



Medical Laboratory Building.

## WASHINGTON

**Society News.**—At the final meeting of the season, speakers before the King County Medical Society were Drs. William B. and Charles R. McCreery, Tacoma, on "The Surgical Attitude Toward the Liver and Gallbladder in 1932"; Siegfried F. Herrmann, Tacoma; "Newer Values in the Application of the Biopsy," and Darrell G. Leavitt, Seattle, "Treatment of Simultaneous Fractures of Tibia and Fibula." Dr. George W. Freeman, Seattle, reported a case of celiac disease.

### GENERAL

**Surgical Journal for the South.**—A new quarterly journal entitled the *Southern Surgeon* was launched in April as the official organ of the Southeastern Surgical Congress. It will be devoted for the present to the publication of papers presented at the annual meetings of the congress. Dr. Launcelot Minor Blackford, Atlanta, is editor and the following surgeons make up the editorial board: Drs. Frank K. Boland, Edgar G. Ballenger and Charles W. Roberts, Atlanta; Hubert A. Royster, Raleigh, N. C.; Willis C. Campbell, Memphis; Rudolph Matas and C. Jeff Miller, New Orleans; William D. Haggard, Nashville; J. Shelton Horsley, Richmond, Va.; Hugh H. Young, Baltimore, and W. W. Harper, Selma, Ala.

**Medical Bills in Congress.**—*Changes in Status:* S. 572, the Jones bill providing for "federal cooperation" with the several states in promoting the welfare and hygiene of mothers and children, was reached twice on the Senate calendar during the week ended June 18, but consideration of the bill was again prevented by Senator King, Utah. S. Res. 26, proposing to change the name of the Senate Committee on Pensions to the Committee on Veterans' Affairs, was debated in the Senate, June 13 and June 15, but no action was taken on the resolution. H. R. 4743 has been reported to the Senate, without amendment, providing for federal subsidies for the promotion of vocational rehabilitation of persons disabled in industry or otherwise (S. Report 821).

**Special Board for Dermatology.**—The American Board of Dermatology and Syphilology has recently been formed to conduct examinations and issue certificates to physicians who are considered qualified to practice as specialists in those subjects. The new board is similar to the boards previously formed for the specialties of ophthalmology, otolaryngology and obstetrics and gynecology. It has eight members, four elected from the American Dermatological Association and four from the Section on Dermatology and Syphilology of the American Medical Association. Officers are Drs. Howard Fox, New York, president; William H. Mook, St. Louis, vice president; Clarence Guy Lane, Boston, secretary, and George M. MacKee, New York, treasurer. Other members are Drs. Jay F. Schamberg, Philadelphia; Howard Morrow, San Francisco; Harold N. Cole, Cleveland, and Arthur W. Stillians, Chicago. The board expects to hold its first examinations during the coming year.

**Plan Second Mental Hygiene Congress.** — The second International Congress on Mental Hygiene will be held in Paris, France, in 1935, it was announced following the first annual meeting of the governing board of the International Committee for Mental Hygiene, held in New York in April. Clifford W. Beers, secretary of both the national and the international committees, is now in Europe making preliminary arrangements. Dr. William Alanson White, Washington, D. C., was elected president and the following were elected vice presidents: Drs. Charles F. Martin, Montreal, for Canada; Joseph Genil-Perrin, Paris, for France; Robert Sommer, Giessen, for Germany; Giulio C. Ferrari, Bologna, for Italy; Adolf Meyer, Baltimore, for the United States, and Sir Maurice Craig, London, for Great Britain. Thomas W. Lamont, New York, is treasurer; Dr. Clarence M. Hincks, New York and Toronto, chairman of the executive committee, and Orlando B. Willcox, New York, chairman of the finance committee.

**Prevalence of Smallpox in 1931.** — Although the total number of cases of smallpox reported in the United States declined from 43,694 in 1930 to 26,000 in 1931, states of the north central and western sections of the country still show a heavy incidence of the disease, according to recent statistics. At least 86 per cent, or 22,413 of the cases, occurred in nineteen states of that section. In fifteen states of the Atlantic seaboard with approximately the same population, only 1,063 cases occurred. The states in which smallpox was most prevalent, amounting to more than 1 case per thousand of population in Kansas and South Dakota, are in general those in which the value of vaccination is not recognized, while in the Eastern states vaccination is the general practice. Certain cities and towns showing high prevalence were listed in the report. In Fort Scott, Kan., 128 cases occurred, which would mean a rate of 1,188 cases per hundred thousand of population; in Helena, Ark., 85 cases, a rate of 1,035, and in Bennington, Vt., 74 cases, a rate of 998; that is, 1 out of every 100 of the population was infected during the year.

### Tuberculosis and Literary Genius

The number of great writers who have suffered from tuberculosis has long been a subject of remark. Some authorities have held that the disease has an effect in promoting mental development. At the Congress of the Royal Institute of Public Health, Dr. S. Vere Pearson, physician to Mundesley Sanatorium for Tuberculosis, delivered an address on the psychology of the consumptive. Referring to such authors as Tchekov, Stevenson, Keats, Elizabeth Browning and D. H. Lawrence, he said that some people ascribed their genius to the stimulating powers of the toxins of tuberculosis. Undoubtedly a sort of restless agitation was produced in certain phases of pulmonary tuberculosis. There was also a feeling of apprehension lest life should be shortened. Both the apprehension and the restlessness might act as a stimulus to production and particularly to the production of authors, who could pursue their calling without much bodily exertion. But the reactions of well known writers to the misfortunes and inconveniences of consumption had been much exaggerated, especially in the case of Stevenson and Lawrence. Authors as much as other persons reacted much more strongly to influences of their environment than to those due to ill health. Lawrence's reactions to his early home life, his marriage, the war and other matters had a greater effect on his character and writings than all the consequences of the prolonged trouble he had with his health. Most of the well known authors who had died from consumption had not had much good treatment for it. That was largely due to their temperaments and the circumstances in which they were placed. Lawrence always resisted the receipt of proper advice from an experienced physician until shortly before his death. Of all modern writers he seemed to have understood best the connection between mental upsets and ill health. At the same time it was erroneous to ascribe much of the peculiarity of his writings to his being a sufferer from tuberculosis. Dealing with the beneficial effects of happiness on the disease, Dr. Pearson referred to the case of Mrs. Browning. In 1842 it was considered a feat for her to be able to walk across a room. Four years later she married Browning and her happy life enabled her to live until 1861. It might be said in criticism of Dr. Pearson's interesting address that he somewhat misses the point, which is not the effect which the trouble of tuberculosis has in molding the writings of authors, but that the toxins of the disease act in some way as a stimulus to the brain in the production of works of the imagination. The list of writers who have suffered from tuberculosis, some, such as Keats, the Brontës and Stevenson, supremely great, is so long as to suggest something more than coincidence.

### Discussion on the Teaching of Obstetrics

In a previous letter (THE JOURNAL, April 30, p. 1577) was reported the criticism by leading teachers of medical education. They considered that the main fault was the overburdening of the curriculum. Now the question of the teaching of obstetrics has been taken up at the Royal Society of Medicine in the Section of Obstetrics and Gynaecology by well known teachers. Mr. Eardley Holland of London Hospital, in opening the discussion, referred to the report of a committee appointed in 1919 to inquire into the teaching of obstetrics and gynecology. No fault was found with the systematic teaching, but the practical instruction was condemned, chiefly owing to lack of facilities for inpatient teaching. An expansion of hospital accommodations for maternity cases was recommended. All that the schools could hope to do was to turn out a reasonably safe practitioner of midwifery, not an obstetric specialist. It was the custom to decry systematic lectures, but he believed in their value, because a difficult subject could be obtained much more vividly than by reading a textbook. As to clinical teaching, he favored a six months course. He found students wofully ignorant of the anatomy and physiology of reproduction, and much of his time was occupied in teaching a student what he should have learned when studying anatomy and physiology. More use should be made of the phantom, on which students should practice maneuvers daily under supervision.

Mr. L. Carnac Rivett of Middlesex Hospital believed in clinical rather than systematic lectures and attached great importance to tutorial classes. Each student should be instructed not only in the actual delivery of normal cases but in all such obstetric operations as he would have to perform later in practice.

Mr. Ninian Falkiner of Rotunda Hospital, Dublin, considered two months residence in maternity hospitals necessary for students. The number of forceps deliveries at the Rotunda was not great, so that they could not teach every student to perform a forceps delivery. He desired to see the gradual development of postgraduate training in conjunction with a special degree.

Mr. W. J. H. M. Beattie of St. Bartholomew's Hospital considered the teaching of gynecology comparatively easy, but obstetrics was more difficult, chiefly because of the large number of students and the small amount of obstetric material. Tutorial and practical demonstrations should take precedence over systematic lectures. Too much attention was paid to the theoretical and academic side of teaching because of the need to pass examinations.

### Presentation of Medal to Sir Charles Sherrington

At a meeting of the Section of Neurology of the Royal Society of Medicine, the Hughlings Jackson gold medal was presented to Sir Charles Sherrington. Sir James Crichton-Browne, the oldest surviving friend of Jackson, whom he first met seventy-two years ago, gave some interesting reminiscences. When in 1875 Jackson published his most important paper on temporary mental defects following the epileptic paroxysm, Sir James sent a copy to a judge who had imposed the death sentence on a man who had epilepsy. The result was that the judge intervened and saved the man's life.

Dr. T. Watts Eden, president of the society, supposed that Jackson would always be regarded as one of the greatest clinical observers the world had ever seen. Sir Charles Sherrington's observations had disclosed a domain of nerve function which was hardly dreamed of in Jackson's time.

Sir Charles Sherrington said that the gift he received in the name of the master of neurology was an encouragement which nothing could exceed. He inspired the laboratory worker as much as he did the clinician. There were enthusiasts who had time to cultivate both aspects. But for Sir Charles the laboratory had always seemed such a busy place that he could not get outside it, though never from lack of interest in what was being done elsewhere.

### Financial Difficulties of Medical Socialism

The government has found it necessary to introduce a bill to insure financial stability of the national health insurance scheme. In the House of Commons the minister of health, Sir E. Hilton Young, said that no fewer than 17,000,000 persons were now insured. For the first ten or fifteen years of the twenty years' life of the scheme, its finances were prosperous and large surpluses were secured, out of which additional benefits were paid. Then came a change. Between 1921 and 1927 there was a startling increase in the sickness claims of married women—to 106 per cent above the expectation. More careful supervision of claims and better medical certification were urged, but without much effect. Then it became obvious that there was something seriously amiss with the finances of national health insurance. Claims were increasing, particularly with respect to women. On the other hand, another menace arose: Owing to the growth of unemployment, contributors were increasingly falling into arrears. Next the actuary reported that while during the period of prosperity the surplus assets of the lodges grew by no less than $125,000,000, during the subsequent period there was no real increase and "additional benefits" had to be considerably reduced. No fewer than 418 societies were faced with a deficiency, and if they could not fall back on central aid they would not be in a position to pay their minimum statutory benefits. The outlook was now critical. To go on as at present would result in a widespread deficiency among the societies. The breakdown with respect to married women was such that the sickness and disablement benefit was $20,000,000 in excess of actuarial expectation during the last valuation period. The loss in respect to married women was three and one-half times greater than in respect to single women. A government investigation led to the conclusion that the main cause of the increased claims was the number of persons who receive benefit although not incapable of work. The government proposes to reduce the disablement benefit of unmarried women from $2 to $1.25 and of married women to $1, and also to reduce the sickness benefit of married women. It has also been found necessary to curtail the extent to which persons are excused arrears of contribution because of unemployment.

### Biologic Effects of Meteorological Factors

At the last Congrès national d'hygiène, it was decided to organize an official conference to study the influence of various meteorological elements on the organisms of man and animals. The program of this conference, which is to be held, July 10, at the Institut de Pasteur de Paris, has now been worked out by the organization committee and communicated to the press, in order to provoke inquiries and to stimulate, in the various countries, medical observations, which the conference will gladly accept. The program is as follows: (1) general statement of the problem; action of various meteorological factors on the organism, to be presented by Dr. Lesage, member of the Academy of Medicine, and former president of the Société de médecine publique; (2) exhibit of instruments and scientific procedures that meteorology can place at the disposal of biology, in charge of General Delcambre, inspector general of aeronautics and director of the Office national météorologique, and (3) scientific bases of statistics: exhibit of the methods that the statisticians can place at the disposal of biology, entrusted to Mr. Moine, statistician of the Comité national de défense contre la tuberculose and director of the Office national d'hygiène sociale. This first conference has for its object the establishment of a scientific basis for the researches that would bear on the following points, the results of which would be presented at a later conference: (1) influence on the healthy human organism, for example, shocks in nurslings, epidemic of Liége; (2) effects on the terrain (receptivity); (3) influence on the organism already infected (malaria, and the like); (4) influence on the progress and extension of epidemics; (5) influence on micro-organisms, and (6) influence on the means of vaccination. In each of these subjects to be considered, the investigator should give an historical account of what has been done and (2) a description of the scientific method to be adopted to serve as a basis for new researches.

### Seasonal Variations in the Virulence of Poliomyelitis

Professor Levaditi of the Institut Pasteur de Paris, who took up some time ago a study of poliomyelitis and directed the inquiry into the epidemic that occurred in Alsace in 1930, has made some interesting new observations. It is well known that poliomyelitis is subject to seasonal variations that have not as yet been explained. Some investigators have invoked cosmic influences, others the electrical condition of the atmosphere, and still others changes in the virus itself. Professor Levaditi and Mr. Hornus observed, in November and December, 1931, that first an attenuation and later a veritable suppression of virulence occurred in a strain of poliomyelitic virus conserved in the laboratory by regular passages through the monkey. They sought an explanation for this phenomenon and presented later to the Academy of Medicine the conclusions that they reached. They found that this disappearance of pathogenic activity took place in vivo owing to a progressive autosterilization of the neuraxis due to a partial and probably seasonal immunity of the organism of the monkey. Comparing their observations on the periodicity, likewise seasonal, of the epidemics of poliomyelitis, they concluded that this periodicity is ascribable to variations in the resistance of the organism of the animal, as determined by its external surroundings, rather than to changes of inherent biologic properties in the microorganism. This opinion is a further elaboration of that outlined by Levaditi last year. He assumes that the poliomyelitic virus, which attacks almost exclusively young persons, finds an increasingly resistant milieu as subjects pass beyond their twentieth year of age, which enables them to play then the rôle of germ carriers. Immunity, in man as well as in the monkey, is therefore established easily, merely with advancing age.

### Professor Bloodgood's Address Before the Anticancer League

The general assembly of the Ligue française contre le cancer was held in Paris, April 26, in the hall of the council of the faculty of medicine. The meeting was a formal occasion. The president of the republic and the ambassador of the United States sent representatives. Other notables present were the minister of public health, the director of the public health service, several professors of the Paris faculty of medicine, the management of the Institut Curie, and many eminent scientists. After the reading of reports of the general secretary and the treasurer, and the election of Professor Forgue of Montpellier as member of the council, the audience assembled in the Great Hall of the faculty of medicine, where Prof. Joseph Colt Bloodgood of Johns Hopkins University, Baltimore, delivered an address, with presentation of a film, on the need of the early detection and treatment of cancer. He praised the work in this field of French scientists and announced also what had been undertaken in the United States. He emphasized the importance of phenomena that, while they do not constitute cancer, may develop into cancer. For the prophylaxis of skin cancer, he recommended that, with the birth of the child, the attention of the obstetrician should be drawn to the slight anomalies; later this rôle diverts to the mothers and to the teachers. He emphasized the value of frequent examination of the buccal cavity by the stomatologist and enumerated the diseases that may originate in the mouth. He studied the rôle of roentgen rays and of radium in the treatment of malignant bone tumors and cancer of the breast, and the importance of radiography for the early detection of these tumors and of cancer of the stomach. Today, the cases in which operation is no longer practicable have been reduced to less than 50 per cent, for it is just as easy to roentgenograph the stomach as it is to examine the heart with a stethoscope, and it is easier to reach a sure diagnosis. In closing, Professor Bloodgood recommended a semiannual pelvic examination of mothers as the surest protection against cancer of the cervix or the uterus. The day following, he presented, at the Faculté de médecine, two other films used to illustrate two further lectures, one on "The Development in Vitro of Human Tumors and of Human Cancer Cells" and one on "The Radiologic Diagnosis of Bone Tumors." Professor Calmette gave a reception in Professor Bloodgood's honor at the Institut Pasteur.

### The Biologic Reactions of Lying

Accounts published in the United States in regard to a recording apparatus (lie detector), designed to reveal the emotions of a defendant in a court action and to detect a lie, awakened interest in France. Dr. Laignel-Lavastine suggested, in this connection, analyses of the urine before and immediately after the examination of a witness, he having noted that the hydrogen ion concentration is modified in subjects in whom the examination had caused great emotion. Several medicolegalists, writing in the *Siècle médical*, stated that they had frequently observed that the sudden acceleration of the pulse and the sharp rise of blood pressure in a defendant when asked an unexpected and embarrassing question often coincided with a fear state, and that the outcome of the inquiry had often shown that at that moment the defendant had lied. But there are causes of error due to the condition of the defendant's heart. If the accused is much depressed, he may have a very weak pulse, which does not vary whether his statements are true or false. The variation in the hydrogen ion concentration of the urine, if collected with a sound, would give, according to Laignel-Lavastine, results less likely to be affected by other factors, a strong emotion creating immediately a state of acidosis. It appears, however, that these laboratory experiments, interesting though they may be from a psychophysiologic point of view, will be difficult to apply practically in connection with the examination of court witnesses.

### Intoxication with Carbon Tetrachloride

Carbon tetrachloride has widespread medical and industrial uses. Employed by dermatologists to combat seborrhea of the scalp and seborrheic eczemas, it does not appear to have caused notable accidents. Used internally to destroy Ancylostoma, it provokes sometimes nervous or hepatic disorders. But it is chiefly when used for the extinguishing of fires that it produces the most serious accidents, several examples of which have been reported recently in various parts of France. Either by its direct action or by its decomposition into carbon oxychloride, it causes grave disorders in persons who have breathed in much of the vapors in the vicinity of a fire combated by extinguishers containing this substance. In the persons affected, one observes trembling, convulsive spasms and even tetanic attacks. In cases of inhalation, even though for only a brief interval, while the nervous signs may disappear rapidly, death may ensue within a few days, due to acute edema of the lungs, bronchial pneumonia or, particularly, hepatic lesions. The lesions found involve almost exclusively the liver; attention has been called to renal lesions in subjects probably predisposed. Dr. Mollaret of Grenoble reported a case of a fire that arose owing to a short circuit, in a poorly ventilated room, which required the use of extinguishers containing carbon tetrachloride, of which a rather large amount was employed. That evening the two men felt a slight discomfort, and the next day they presented a subicteric appearance and complained of nausea, gastric disturbances, and a profound asthenia. The symptoms remained intense for four days and then steadily diminished during the following week and ended in recovery. Drs. Hébert and Phélebon of Montrichard published their observations on an automobile chauffeur who had been cleaning for several hours the chassis of his vehicle by means of a carbon tetrachloride product used normally as a fire extinguisher. The following day, he was seized with vomiting and presented a subicteric appearance with hepatomegalia and azotemia. A cure was effected as the result of energetic treatment. It is to be noted in this case that the intoxication was not due to the projection of carbon tetrachloride on a fire but to the inhalation of the cold product, for several hours, in a confined atmosphere. The council of health has consequently decided that cleaning operations with carbon tetrachloride should be carried on in the open air. For the extinction of fires one should, as far as possible, combine the use of carbon tetrachloride with that of other products (water extinguishers using foam or spray). When one has recourse to this method, one must beware of fires of electrical origin developing in poorly ventilated spaces: for example, in cable conduits. In that case, it is well to equip the rescuers with gas masks.

## BERLIN

May 16, 1932.

### Organization of Cancer Research

The organization of cancer research, as has already been emphasized, is at present in the forefront of interest, whereas, for a number of years previously, it had received little attention. Mention has been made of the appointment of a federal commission to supervise and aid in the organization of cancer research (The Journal, May 30, 1931, p. 1887). The council of the federal commission for cancer research met recently in Berlin, under the chairmanship of Ministerial Director Dr. Dammann, at the federal ministry of the interior. Since others besides physicians are interested in the movement to spread a knowledge of cancer, the criteria for the organization of cancer research must, in their form of expression, take account of that fact. As representing the aim of organization measures, the following criteria have been proposed: the early detection of cancer patients and examination of suspects; the rapid and sure diagnosis of cancer; the aid of cancer patients after receiving treatment. The aid of incurables must not be neglected. Success depends primarily on the cooperation of the physicians, supported by suitable auxiliary forces and the population, after it has been properly enlightened on the subject of cancer. Since, aside from occupational cancer, there is no prophylaxis against cancer in general, the aim of the publicity campaign must be to induce persons with suggestive signs to submit to an immediate and adequate medical examination. The education of the people in the hygiene of cancer must be carried on in such a manner as to counteract fear of the disease. Attention should be called to the fact that cancer, if diagnosed in time, no longer belongs to the incurable diseases. Especial significance is attached also to promulgating a better knowledge of cancer among the physicians. The most important tasks of organization rest with the state and the provincial committees. The following should take part in the work: representatives of the governments and the administrations of the provinces, of the cities and the rural communities, of the medical profession and of the faculties of medicine, the social aid agencies and the volunteer public welfare agencies.

The example of Sweden and France was called attention to by many as worthy of imitation by reason of a centralization of cancer treatment. In spite of this suggestion, however, the criteria as drawn up were based on the principle of the natural development dictated by the conditions obtaining at present in Germany. It would be virtually impossible and certainly not feasible to try to take the cancer patients away from the surgeons and gynecologists and from the smaller and middle-sized pathologic institutes directed by them, since they are in a position to treat them by purely surgical means. That is not done even in Sweden, as is known from Forsell's public statement, although Sweden is usually put forward as a prototype of centralization. The utmost endeavors must be put forth to provide institutions in which cancer patients can be treated by methods that are in accord with the present status of medical knowledge.

Especial importance attaches to the providing of sufficient funds to assure the examination of cancer suspects and the prompt and effective treatment of all cancer patients. Aside from suitable agreements between the guarantors of the cost of treatment, concerning the continuation and the avoidance of interruption of therapeutic measures already begun, the collection of a general fund was proposed in order to assure for patients of limited means who have no one to guarantee the cost of treatment an immediate examination and prompt treatment.

According to the papers of Dietrich of Tübingen and Stauder of Nuremberg, in view of the improvement in the statistics and the assurance of good results from treatment, a movement in favor of voluntary submission to examination and treatment ought to be organized by the medical profession, as has been done in some parts of the country, with suitable participation on the part of the "chambers of physicians" *(aerztekammern)*. The federal cancer commission has decided to promote this idea more vigorously through the appointment of a small committee of experts.

### Are Fixed Prices for Courses of Treatment Feasible?

Like all other institutions, the mineral spring bath establishments have endeavored to accommodate themselves to economic necessities and changed conditions. On every hand, courses of treatment at fixed prices are announced. While this innovation appears to meet a present-day need, there is a possibility of the treatment becoming thereby too mechanical, and precisely in connection with treatment at mineral spring resorts evils may arise as a result of such a system. The physicians and the managements realize the dangers involved; but there is naturally enough a desire to relieve in this manner the not always unjustified fears of the patients that a course of treatment extending over several weeks may exceed the limits of their capacity to pay. One hears on every hand the complaint that spa treatment has become much more expensive. These complaints are unjustified in that it is impossible to state in advance what the exact cost of treatment will be, in view of the fact that the extent of the treatment needed becomes apparent only during the course of the treatment. Hence, many voices are raised against soliciting patronage by offering fixed prices for prolonged courses of treatment, it being alleged that it would be much better to reduce the charges for diagnostic measures and for treatments to as low a point as possible, and thus avoid unprofessional mechanization. What is true of therapeutic measures to be applied in spas and in sanatoriums is true also —allowing for slightly changed conditions—with reference to observation patients in hospitals, and particularly in private clinics. This applies to observation cases in the field of the internist, the surgeon, the urologist and others. Many a patient dreads an observation extending over several days on account of the heavy expense for special diagnostic aids, in which the roentgenologic examination is nearly always the principal component. But also chemical and physical examinations, functional tests, and the like, go to make up a sum, which, along with the regular hospital charges, is considerable, and there is a danger that little will be left to pay the physician's fees. There have been attempts to establish a fixed, previously announced price for the diagnosis of circulatory disturbances, gastro-intestinal disorders, and liver and gallbladder disease. Some of the plans that looked enticing when viewed theoretically have been found impracticable when it came to their execution. A hospital observation, with the application of modern diagnostic methods, is not usually undertaken unless a simple clinical examination fails to accomplish its purpose. If a fixed price is made, the examiner is obliged to confine himself to one organ or to one organic system. But it is well known that, not infrequently, in searching for a stomach ulcer the examination must be extended to the gallbladder, to the large intestine, and possibly to the renal pelvis. Such an eventuality plays havoc with a fixed price agreement. It would appear, therefore, that these endeavors to give a fixed price in advance, while well meaning enough, may be regarded as mere transitory attempts to adapt oneself to the changed economic conditions that prevail.

## THE UKRAINE

*(From Our Regular Correspondent)*

Odessa, April 28, 1932.

### The Third All-Ukrainian Therapeutic Conference

The Third All-Ukrainian Therapeutic Conference was held in Kiev, Sept. 10-15, 1931. On the first day, the attention of the conference was held by Prof. M. I. Leporsky's paper on "The Pathogenesis and Treatment of Acute Joint Rheumatism." Professor Leporsky pointed out that most investigators agree on the infectious or allergic theory.

Studying basal metabolism during rheumatism, Professor Leprosky found in the daily balance a retention of water and sodium chloride without hydremia or an increase of sodium chloride in the blood, an increase in the total and residual nitrogen in the blood, and a diminution in the basal metabolism of 23 per cent on an average. Connecting these facts with Pemberton's data on the increase of blood oxygen in the course of rheumatism, Professor Leprosky concludes that there is an increase of albumin metabolism, a retention of water and a limitation of oxidative processes in the tissues. As to treatment, Professor Leporsky removes any local septic foci and prescribes Pemberton's diet. He obtained good results using this treatment.

The problem of rational nutrition was one of the topics for discussion. Dozent L. K. Korovitzky discussed pellagra. During 1929-1931 he observed about 560 cases of pellagra in South Ukraine. He makes the following conclusions: Physicians often mistake indistinct forms of pellagra for skin diseases. The early symptoms of pellagra are salivation, obstinate diarrhea and skin manifestations. From a group of Dozent Korovitzky's sixty patients, all from one city, 50 per cent never eat maize; thus it did not enter into the etiology of the disease. The principal causes of pellagra are an unbalanced diet with insufficient protein and deficiency of vitamin $B_2$ in the food.

Prof. V. M. Cogan-Iasni read a paper on the pituitary diseases. He demonstrated the treatment of diabetes insipidus by means of transplantation of the pituitary. Clinical observations completely confirm the rôle of the hypophysis cerebri in the regulation of water balance and pathogenesis of diabetes insipidus. The cooperation of physiologists, biochemists and clinicians is necessary in the study of hypophyseal disorders.

Among the papers not included on the program was that of Prof. X. X. Vlados of Moscow on pernicious anemia of the Biermer type, treated by the method described by W. B. Castle (*Am. J. M. Sc.* **178**:748 [Dec.] 1929). He also treated with good results pernicious anemia patients with mucin from hog stomachs.

About 400 physicians, chiefly from the Ukrainian Socialist Soviet Republic, were present at the conference. The subjects on the program of the next conference will be the problem of influenza, stomach diseases and circulatory diseases.

Prof. I. I. Fainschmidt was elected president of the organization committee from the Ukrainian Socialist Soviet Republic.

### The Death of Professor Goubarev

Alexander Petrovitch Goubarev died, Oct. 23, 1931, of arteriosclerosis. He was born in 1855 in Moscow, where he graduated in 1889 from the medical faculty. In 1889 he was invited to be prosector to the chair of anatomy under Professor Zernov; at the same time he worked in the gynecologic clinic under Professor Snegirev. In 1893 he was elected professor of gynecology and obstetrics in the university of Dorpat, and in 1898 became professor in the same chair in Moscow. He was director of the gynecologic clinic of the First Moscow State University constantly until 1922, when he retired because of ill health.

Professor Goubarev has written 131 scientific works, many of which are in English, French and German. His "Operative Gynecology" and "Clinical Anatomy of Female Pelvic Organs," which he illustrated himself, received premiums. He was one of the founders and editors of the journal *Gynecology and Obstetrics*. He founded a school of Russian gynecologists and obstetricians. In 1911 he was elected Doctor of Science Honoris Causae of the Dublin University. He was an honorary member of many European and Russian gynecologic and obstetric congresses and societies.

### The Treatment of Trachoma

The soviet government has begun an intensive campaign against trachoma. Of the total number of blind persons in the Soviet Union, 234,833, one fifth lost their vision because of trachoma.

For the rational treatment of trachoma, Professor Phylatov of Odessa proposes to limit the use of drugs, reducing the treatment to frequent pressing out of the granules, the operation that is acknowledged as the best method of treatment. He advises that this intervention be repeated several times at intervals of from four to six weeks. The loss of the patient's time by this operation is compensated for by abolishing medical treatment, for which frequent visits to the hospital are necessary. The effectiveness of the treatment depends on the active stimulation of the local tissue reaction. In the treatment of sixty patients in Grossliebenthal, a village near Odessa, and in Luxemburg, a village near Marieoupol, the author and his collaborators secured good results. There were no complications in more than 400 cases which did not receive any further treatment.

## MADRID

*(From Our Regular Correspondent)*

May 2, 1932.

### The International Congress of Surgery

#### TUMORS OF THE SPINAL CORD

During the International Congress of Surgery, recently, in Madrid, Dr. Robineau of Paris presented an article based on sixty-four operations for tumors of the spinal cord, performed by himself. Death occurred in one case following hemorrhage and in two cases from cardiac syncope eighteen and twenty hours after the operation. Tumors of the spinal cord are fatal unless surgically removed. The diagnosis should be made early. The clinical diagnosis should be confirmed by the laboratory examinations with regard to the modifications of the cerebrospinal fluid, the pressure of the cerebrospinal fluid and the radiologic examination of the subarachnoid space, after the injection of an opaque iodized oil as a contrast medium. The oil stopped by the tumor shows its outline. In the presence of such conditions as Pott's disease or some types of myelitis it is possible to make a mistaken diagnosis of tumor of the spinal cord. In certain cases it is impossible to distinguish whether or not the pathologic process is a true tumor or an inflammatory condition. In cases of doubt, it is preferable to operate. Death following the operation occurs in 5 per cent of the cases. Diffuse intramedullary tumors cannot be removed. The life of patients with diffuse glioma who have been operated on may be greatly prolonged by postoperative roentgen irradiation. Flaccid paraplegia caused by destructive medullary lesions as well as spastic paraplegia of old duration do not disappear after the operation. Tumors with extensive intramedullary ramifications cannot be totally removed, because of the danger of sacrificing essential nerve cells during the operation, and their recurrence after the operation is fatal. The operation gives satisfactory results in 60 per cent of the cases, in 50 per cent of which no functional disturbances persist after some months following the operation. Surgery of tumors of the spinal cord is one of the achievements of neurology during the last four decades.

Dr. Dominici of Rome presented statistics covering sixty-three cases of intraspinal tumors. The tumor could not either be found or reached in five patients; three patients died as a result of the operation; in the remaining fifty-three patients the cause of the spinal disturbances was intraspinal tumors, cysts, gummas or fibrous or serous meningitis. The postoperative mortality is higher for tumors located in the superior portion of the spinal cord. The diagnostic method most frequently used in Italy is the descending injection of iodized oil. Radiography is the best method to establish the diagnosis and also to locate the tumor in relation to the vertebrae. In doubtful cases Dr. Dominici resorts to exploratory laminectomy, according to Alessandri's method.

Dr. C. A. Elsberg of New York presented a study of tumors of the spinal cord with statistics on 208 cases, with a postoperative mortality of 6.9 per cent for extramedullary tumors and 1.7 per cent for extrameningeal tumors. The following results were obtained: complete recovery or considerable improvement in 63 per cent of the cases, a minimal improvement in 10 per cent and no modification of the conditions in 18 per cent; in five cases the results were not reported. The tumors were seated in the thoracic region in 51 per cent of the cases, in the cervical region in 32 per cent, and in either the sacral or the lumbar regions in 17 per cent of the cases. The tumors were intrameningeal in 72 per cent of the cases and extrameningeal in 28 per cent. The content of total globulin and protein in the cerebrospinal fluid is higher when the tumor is intradural than when it is extradural.

Dr. Mixter of Boston originated a method to prove the presence or absence of an intraspinal tumor above the operative field during the operation. As soon as the arachnoid membrane is located, the assistant makes digital compression on the veins of the neck. The absence of any pathologic lesion which may cause obstruction of the arachnoid space above the operative field is proved by the free passage of the fluid from top to bottom through the arachnoid space while the veins are under compression.

### CARDIOSPASM

Dr. L. Cardenal of the Faculty of Medicine of Madrid discussed cardiospasm, which he defined as "a functional disturbance of the cardiac sphincter, during the passage of food into the stomach, followed by hypertrophy and dilatation of the esophagus, without the presence of an anatomic stenosis." The condition does not indicate a spasm but a dilatation of the esophagus, the pathogenesis of which is similar to that of congenital stenosis of the pylorus and to congenital hypertrophic dilatation of the colon. The identity in the pathogenesis of these conditions becomes evident by an interpretation of the laws of Bayliss and Starling on the mechanism of peristalsis. This may explain the production of disturbances in some other sphincters, as well as some postoperative disturbances related to the passage of food through the new anastomosis made in operations on the stomach. The esophagus is permanently separated from the stomach and opens into it, through the cardiac sphincter, only during brief periods as the result of a physiologic reflex caused by deglutition. The cardiac sphincter represents a vegetative muscle. Smooth muscles resist pressure and traction for a long time without consumption of energy. But they are not true sphincters, since Kastner defined true sphincters as muscles with tonus, which do not have various dimensions but only variations of tension, and which do not follow the laws of peristalsis given by Bayliss and Starling. The cardiac sphincter of the esophagus follows these laws. In normal conditions the cardiac sphincter is in an intermediary condition between maximal contraction and maximal dilatation. If one stimulates mechanically the wall of the pharynx, one can observe a peristaltic movement which runs the entire length of the esophagus. In the same manner, the passage of food through the pharynx causes in the esophagus a wave of dilatation, which is immediately followed by a wave of contraction. The latter, however, is more imaginary than real, since it is only the return of the esophageal segment to its original position. The active phenomenon of stimulation causes the opening of the esophageal segments that are immediately under its influence, and while this movement progresses downward, the passive phenomenon, that is, occlusion, takes place in the segments previously dilated. A peristaltic wave of opening on the epicardia permits the passage of the food, but as soon as the food passes through a given segment into another, the first epicardial muscular segment returns to its previous condition of occlusion. If one studies the blood supply of the cardiac sphincter of the esophagus during its phase of rest or occlusion, one can prove that the active phase is dilatation while the passive phase is occlusion. The blood supply of the cardiac sphincter corresponds to the minimal amount necessary for the conservation of the cells. During the spasmodic contraction an almost absolute ischemia of the contracted segment is noticeable, while the circulation is considerably increased during the phase of relaxation. The experimental ligature of the local vessels causes ischemia and prevents the opening of the cardiac sphincter. In cases with a pathologic increase of circulation (such as peritonitis or mediastinitis) the cardiac sphincter is dilated, relaxed and patent. Bayliss and Starling in 1899 established a law with regard to the peristaltic movements of the digestive tract according to which any natural stimulation on the intestinal mucosae causes at the same time dilatation of the intestinal segment immediately under the influence of the stimulus and contraction above it. According to the law of Bayliss the dilatation (which starts immediately below the stimulated point and follows in a movement of propagation downward all through the digestive tract) is not a relaxation caused by inhibitive impulses but a manifestation of activity of all the vascular and muscular cells of the intestinal mucosae. The following contraction is only the return to a condition of rest of the segments.

### SURGERY OF THE ESOPHAGUS

Dr. Gregoire, of the Faculty of Medicine of Paris, stated that the progress of surgery depends on advances made in the examination of the patient, in pathology, and in the treatment of cases. From these points of view, surgery of the esophagus has made great progress in the last few years. Roentgen examination of the esophagus and endoscopy are of great value, and by these methods intra-esophageal treatment has brought good results. The pathology of ulcer, diverticula and idiopathic dilatation of the esophagus has advanced. A more precise operative technic has been developed to approach the mediastinal esophagus, especially at the level of its inferior segment. By the use of extraserous methods, the dangers of the infection of the pleura and of the peritoneum have been avoided.

Dr. J. L. Faure of Paris stated that, although he performed two operations with resection of the thoracic segment of the esophagus thirty years ago, at present he has supplanted the operation by roentgen therapy.

Dr. Sauerbruch of Berlin said that he has successfully operated in four cases of esophageal diverticula opened into the bronchi; he performed esophagogastric anastomosis in twelve cases without having had a death; in two cases of cancer of the esophagus invaginated into the cardiac sphincter, he succeeded in resecting the pathologic segment in a one-stage operation.

### PROGRESS IN SURGICAL ANESTHESIA

Dr. Monod of Paris said that rectal anesthesia should be resorted to only in exceptional cases, because the absorption through the intestine is irregular and the anesthesia cannot be controlled. Anesthesia with tribrom-ethanol is pleasantly mild and patients prefer it to spinal anesthesia. Ether anesthesia given as a mixture of ether in oil is less dangerous than tribrom-ethanol anesthesia and the dose of the anesthetic does not have to be repeated. Ether has a less irritative action on the rectum than tribrom-ethanol, and its anesthetic effect is more prolonged. The principal indications of ether anesthesia are for operations on the thorax, the neck and the head. The toxicity of tribrom-ethanol limits its use. It is especially of value in operations performed on weak persons and in operations of long duration; its use is not followed by any disturbances that usually follow any other anesthetic by inhalation. Theoretically, tribrom-ethanol is not the best anesthetic for the following reasons: It demands the constant supervision of an expert anesthetist during the operation; the anesthetic effects are rapid; the enema should be given at a temperature not higher than 40 C. (104 F.), since when it is given at a higher temperature it becomes irritative to the rectal mucosae and may cause necrotic colitis. The sensitiveness of the respiratory center to tribrom-ethanol is even greater than to chloroform, and tribrom-ethanol depresses the blood pressure. An excessive dose of tribrom-ethanol is dangerous. Killian in 1927 reported 33 deaths among 3,646 operations made under tribrom-ethanol anesthesia. Sixteen out of the thirty-three deaths were undoubtedly caused by the anesthetic. By improvements in the technic, better results have been reported from Germany among 400 operations done under tribrom-ethanol anesthesia. Lundy believes that the mortality rate from tribrom-ethanol anesthesia is 3 per thousand, while Sprecht believes it is 1 per thousand. The dose of tribrom-ethanol is 0.1 Gm. per kilogram of body weight. Then the solution should be diluted in water distilled twice in a proportion of 2.5 per cent; that is, 6 Gm. of tribrom-ethanol and 240 cc. of water distilled twice. The solution is made up in an Erlenmeyer's flask to a temperature of 40 C. Great care should be taken not to exceed this temperature. The solution is shaken in the bottle during five minutes and it is prepared in the same manner in which arsphenamine is prepared; that is, at the time that it is going to be used. Before the injection is given, 5 cc. of the solution is poured into a test tube to which a drop or two of a 1 per cent solution of congo red is added. The color given by this mixture should be a clear orange red. If the mixture has a bluish hue it should not be used because it is dangerous. The enema is given by using a catheter with a diaphragm in order to avoid escape of the anesthetic. After the solution has been injected, the catheter is closed with a hemostat and left in the rectum for fifteen or twenty-five minutes, until the effects of the anesthesia begin to appear.

Dr. Goyanes of Madrid spoke on arterial anesthesia by injecting inside of the arteries a 0.5 per thousand solution of procaine hydrochloride. By this method, operations in the area supplied by the arteries injected can be made without any pain. The principal indications of this method are operations in the left arm. The effect of the anesthetic lasts all the time during which ischemia is present.

### Superior Board on Psychiatrics

The department of the interior has nominated several psychiatrists to form a superior board on psychiatrics, with Dr. G. Lafora as president. The duties of the board will be to act as consultants and inspectors of psychiatric dispensaries and to promote their establishment; to collaborate with architects appointed to erect psychiatric hospitals; to attend to the prevention of mental disease and to the care of psychiatric patients, and to modernize psychiatric hospitals. The superior board on psychiatrics requested the government to provide the provinces with two different types of psychiatric hospitals: small hospitals of about 150 or 200 bed capacity, built in the city, in which patients with a recent development of the disease may be attended, and larger hospitals, built in rural areas, which may serve as interprovincial or regional psychiatric hospitals, to which patients with mental diseases who have been attended for more than one year in the small hospitals may be transferred. The authorities of Galicia decided to carry on this project. The members of the superior board on psychiatrics requested from the ministry of public education the creation of a chair of psychiatrics in the several schools of medicine in order that the personnel in charge of psychiatric hospitals may be selected from specialists who have attended those courses. The board will also select the nurses. Through the efforts of the board, a society for the guardianship of psychiatric patients has been organized. Members of this society are well known laymen who will help the board by taking charge of certain chronic patients who are not dangerous; they will help them to live in better conditions to bring about their social adjustment by placing them or helping to support them as guests of families who live near the psychiatric hospitals. In some Spanish hospitals it has been estimated that 60 per cent of the psychiatric patients develop tuberculosis in about six months after admittance.

### Eightieth Birthday of Ramon y Cajal

The histologist S. Ramon y Cajal has passed his eightieth birthday. Besides the studies made on histology, Ramon y Cajal founded a school of research on the histology of the nervous system. The anniversary of Ramon y Cajal passed unobserved by his pupils and friends and it appeared only among the news of some daily papers. When Ramon y Cajal was 70 years old, a bust of him was unveiled. Some politicians at that time grasped the opportunity to make a hostile manifestation against the government, which manifestation failed through the efforts of Ramon y Cajal. Those friends who heartily greeted Ramon y Cajal on his seventieth anniversary failed to remember his eightieth anniversary. Dr. Ramon y Cajal works now with the same energy as when he was 50. He feels he should work continuously to complete many of his important researches as soon as possible. The changes of weather affect his health, so during the last winter he lived in an artificial atmosphere while working, so as not to lose time. He spent his eightieth birthday, as every day of his life, over his microscope.

### A Philanthropist Dies

The Marques de Valdecilla, a well known Spanish philanthropist of Santander, died. He gave a great part of his fortune (which was made in America) to universities and hospitals and in promoting medical education. He was the founder of the Hospital Valdecilla of Santander, which he supported. He gave 25,000,000 pesetas ($2,500,000) to medical schools and hospitals. Since rich persons in Spain are few, the fortune of Marques de Valdecilla was considered fabulous and everybody praises him for giving a large part of it to the benefit of mankind. He will always be remembered with respect and admiration.

---

## Marriages

Charles J. Weigel, River Forest, Ill., to Miss Mary Beatrice Rooney of Amboy, June 4.

Willis E. Elder to Miss Elsie Schneider, both of Columbus, Ohio, at Cannonsburg, Pa., May 7.

James Clayton Brown, Valparaiso, Ind., to Miss Mary Birdwell Davis of Elwood, May 8.

F. Dennette Adams, Boston, to Miss Elliott O. Blanc of New York, May 21.

Leon N. Sussman to Miss Evelyn Kaufman, both of New York, June 8.

# Deaths

**Thomas Patrick Hennelly** ⊕ Pittsfield, Mass.; Harvard University Medical School, Boston, 1908; past president of the Berkshire District County Medical Society; fellow of the American College of Surgeons; on the staffs of the House of Mercy Hospital, St. Luke's Hospital and Crippled Children's School, Pittsfield, and the Fairview Hospital, Great Barrington; aged 50; died, May 19, of heart disease.

**Thomas Appleton Cope,** Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1900; member of the Medical Society of the State of Pennsylvania; assistant professor of medicine at the University of Pennsylvania Graduate School of Medicine; pathologist to the Germantown Hospital; aged 53; died, May 27, of heart disease, while on a boat trip in Maryland.

**Rewellien Cornelius Peters,** Allentown, Pa.; Medico-Chirurgical College of Philadelphia, 1898; member of the Medical Society of the State of Pennsylvania; past president of the Lehigh County Medical Society; member of the school board; aged 62; died, May 19, of arteriosclerosis and cerebral hemorrhage.

**William Ernest Fleet,** Cambridge, Mass.; College of Physicians and Surgeons, Boston, 1893; Tufts College Medical School, Boston, 1895; member of the Massachusetts Medical Society; aged 59; died, May 25, of hypertension, arteriosclerosis, cerebral hemorrhage and hypostatic pneumonia.

**Charles A. Zinn,** Frankfort, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1897; member of the Indiana State Medical Association; health officer of Frankfort; aged 58; on the staff of the Clinton County Hospital, where he died, May 22, of cerebral hemorrhage.

**Heralda Palma Tyng,** San Francisco; Hahnemann Medical College of the Pacific, San Francisco, 1917; member of the Associated Anesthetists of the United States and Canada; aged 40; died, May 1, in the Franklin Hospital, of acute hemorrhagic nephritis and puerperal eclampsia.

**Edward Beecher Nims,** Springfield, Mass.; University of Vermont College of Medicine, Burlington, 1864; member of the Massachusetts Medical Society; member of the American Psychiatric Association; Civil War veteran; aged 94; died, May 24, of chronic nephritis.

**William Gue Morgan,** Woodward, Iowa; Rush Medical College, Chicago, 1891; member of the Iowa State Medical Society; on the staff of the Hospital for Epileptics and School for Feebleminded; aged 64; died, May 17, of cerebral hemorrhage.

**Alfred Long Gaither** ⊕ Lieut., U. S. Navy, San Diego, Calif.; University of Pennsylvania School of Medicine, Philadelphia, 1918; entered the Navy in 1921; on the staff of the U. S. Naval Hospital; aged 38; died, April 10.

**Irwin T. Medsker,** Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1904; member of the Indiana State Medical Association; aged 55; died, May 14, in St. Vincent's Hospital, of injuries received in a fall.

**Norris A. Smith,** Lineville, Iowa; Kansas City (Mo.) Medical College, 1905; aged 53; died, May 13, in the Wright Hospital, Trenton, Mo., of injuries received when the automobile in which he was driving was struck by a train.

**Charles Sumner Morley,** Holly, Mich.; Homeopathic Hospital College, Cleveland, 1876; for many years on the staff of the Grace Hospital, Detroit; aged 80; died, May 28, of intestinal obstruction and cardiac decompensation.

**Humphrey D. Robinson,** Manistee, Mich.; Detroit Medical College, 1884; member of the Michigan State Medical Society; on the staff of the Mercy Hospital and Sanitarium; aged 74; died, May 14, of heart disease.

**George Hiram Robbins** ⊕ Madison, Wis.; Rush Medical College, Chicago, 1915; formerly assistant professor of clinical medicine, University of Wisconsin Medical School; aged 42; died, May 26, of cerebral hemorrhage.

**Gamaliel C. Myers,** Dayton, Ohio; Cincinnati College of Medicine and Surgery, 1880; Civil War veteran; for twelve years on the staff of the Miami Valley Hospital; aged 84; died, May 24, of cerebral hemorrhage.

**Henry E. Johnston,** Oshkosh, Wis.; Chicago Homeopathic Medical College, 1893; member of the State Medical Society of Wisconsin; aged 67; died, May 22, in Edwardsburg, Mich., of a wound inflicted with a knife.

**Edward S. Gooch,** Lawton, Okla.; Hospital College of Medicine, Louisville, Ky., 1896; member of the Oklahoma State Medical Association; on the staff of the Southwestern Hospital; aged 62; died, April 14.

**Oscar Hasencamp** ⊕ Toledo, Ohio; University of Tennessee Medical Department, Nashville, 1887; aged 68; on the staff of St. Vincent's Hospital, where he died, May 20, of bronchopneumonia and cystitis.

**Woodson T. Merchant,** Louisville, Ky.; Howard University School of Medicine, Washington, D. C., 1888; on the staff of the Red Cross Hospital; aged 70; died, May 13, of secondary anemia and gastric carcinoma.

**Charles Francis McCaffrey** ⊕ Somerville, Mass.; Harvard University Medical School, Boston, 1903; on the staff of the Somerville Hospital; aged 55; died, May 20, of coronary sclerosis and thrombosis.

**Whedon Worley Mercer** ⊕ Chillicothe, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908; aged 47; died, May 20, in the Proctor Hospital, Peoria.

**Leo A. Wilkinson,** Colfax, La.; University of Nashville (Tenn.) Medical Department, 1907; county coroner; aged 49; died, May 9, in the Baptist Hospital, Alexandria, of appendicitis and peritonitis.

**Charles Augustus Henry, Jr.,** Fostoria, Ohio; Rush Medical College, Chicago, 1901; member of the Ohio State Medical Association; aged 55; died, April 6, in the Cleveland Clinic Hospital.

**Walter C. Goss,** Johnson City, Tenn.; Tennessee Medical College, Knoxville, 1902; medical superintendent of the Elizabeth Goss Memorial Hospital; aged 61; died, May 12, of nephritis.

**Frank Collins Garvey** ⊕ Scranton, Pa.; Medico-Chirurgi College of Philadelphia, 1909; on the staffs of the Me Hospital and the Scranton State Hospital; aged 49; di April 17.

**Harry Holmcombe Nelden,** Stanhope, N. J.; Bellev Hospital Medical College, New York, 1891; bank presiden formerly mayor of Stanhope; aged 61; died, May 22, of hea disease.

**Robert Maffet Palmer,** Johnstown, Pa.; Jefferson Medica College of Philadelphia, 1913; member of the Medical Society of the State of Pennsylvania; aged 43; died, May 11, of heart disease.

**James Morgan O'Connell,** Ponca, Neb.; Rush Medical College, Chicago, 1881; member of the Nebraska State Medical Association; aged 79; died, April 13.

**Green V. Daniel,** Paintsville, Ky.; Tennessee Medical College, Knoxville, 1901; aged 66; died, April 6, in the Stephenson Hospital and Clinic, Ashland.

**Martin J. Palmer,** Los Angeles; Eclectic Medical Institute, Cincinnati, 1888; aged 71; died, May 14, of carcinoma of the bladder and prostate and uremia.

**Frank Fisk Casseday,** Portland, Ore.; Hahnemann Medical College of Philadelphia, 1879; aged 76; died, April 22, of cirrhosis of the liver.

**Jeremiah Noble Hankins,** Milton, Fla.; Memphis (Tenn.) Hospital Medical College, 1901; aged 52; died, May 20, of chronic myocarditis.

**John Wesley Gillespie,** Albany, Ga.; University of Georgia Medical Department, Augusta, 1892; aged 69; died, May 20, of senile dementia.

**Myron G. Rood,** Stevens Point, Wis.; Medical College of Ohio, Cincinnati, 1882; aged 73; died, May 27, of acute dilatation of the heart.

**William Arthur Singleton,** Port Huron, Mich.; Detroit College of Medicine, 1912; aged 56; died, May 22, in a local hospital.

**James E. Goldsby,** Gleason, Tenn.; University of the South Medical Department, Sewanee, 1901; aged 72; died in May.

**Anna Moon Randolph,** Hampton, Va.; Woman's Medical College of Pennsylvania, Philadelphia, 1899; aged 67; died, April 8.

**Millard F. Deeren,** Macksburg, Ohio; Columbus Medical College, 1887; aged 72; died, May 26, of diabetes mellitus.

**Corwin F. Howard,** Deepwater, Mo.; American Medical College, St. Louis, 1883; aged 76; died, April 9.

**John H. Imme,** Ottawa, Ill.; Eclectic Medical Institute, Cincinnati, 1880; aged 76; died in April.

# Bureau of Investigation

## ADULTERATED OR MISBRANDED PHARMACEUTICALS

### A List of Some of the Notices of Judgment Issued Between January and June, 1931, Inclusive, by the Food and Drug Administration, U. S. Department of Agriculture

[For many years, the Bureau of Investigation has published in this department, brief abstracts of Notices of Judgment issued by the Food and Drug Administration of the United States Department of Agriculture against "patent medicines." The number of proprietary preparations of this type that each year are found misbranded or adulterated is so large that these abstracts have to be published frequently.

The same officials that deal with cases of adulteration and misbranding in proprietary package medicines also, of course, act to protect the public against adulterated or misbranded official pharmaceuticals. As most official products are made by reputable pharmaceutical houses, the number of cases of adulteration or misbranding in this particular group is small compared with cases in the "patent medicine" group. For this reason, the Bureau of Investigation has made a practice of abstracting each year such Notices of Judgment as have been published by the government during the previous calendar year. We present, at this time, a list of the Notices of Judgment issued during the first half of 1931 dealing with pharmaceuticals. These are arranged alphabetically by products. First is given the name of the product, then follows the name of the manufacturer, shipper, or consigner; finally the number of the Notice of Judgment and its date of issue. It is to be borne in mind that the dates of publication of the Notices of Judgment are always several months later than the date of seizure of the product.]

## EFFECTS OF RADIUM AND RADON GAS TAKEN INTERNALLY

*To the Editor:*—The papers all over the United States have had articles reporting the death of Eben M. Byers from a "patent medicine" that he had been imbibing for the last two years, containing radium. Considering the cost of refined radium, it stands to reason that there was only an infinitesimal amount, if any, of the element present in the "patent medicine" under consideration; hence radium in the form of carnotite or uranium ore was used, containing many other ingredients besides radium that could have caused the ill effects reported. Have any tests been made on niton gas, or radon for internal use, and if so what would be the results of taking this gas suspended in water into the system for the amelioration or cure of various metabolic ailments? I have a number of patients taking radon emanations in water, 2,000 mache units in a liter of water daily, and the majority report excellent results; a few report no change, but none has reported, so far, any actual ill effects. Some of the patients have taken this remedy to the exclusion of all else for six months or more, most of them for lesser time. I am using an emanator, to produce radon gas, manufactured in this city (Los Angeles) by the Zimmer Laboratories, Bendix Building.

A. S. Waiss, M.D., Los Angeles.

Answer.—This question was referred for reply to Dr. Frederick B. Flinn, Columbia University, who made special studies of the case of Mr. Byers. Dr. Flinn writes:

"The death of Mr. Eben M. Byers was caused by the ingestion of radioactive material over a period of months. Electroscopic tests, the history and the clinical picture leave no doubt in the matter. The necropsy confirmed the diagnosis. The whole picture was the same as that presented by the cases of "radium poisoning" among dial painters. Pneumonia was one of the accidental terminal conditions. Phosphorus did not enter into the picture in any manner. Attempts of the physical therapist who recommended Radithor to Mr. Byers to cloud the issue by saying that the death "was the result of a combination of blood diseases which induced gout" shows a deplorable ignorance in the matter. Mr. Byers had an anemia, which is always present in radium cases in the advanced stage, but there was no evidence of gout during the year that I saw him. It might be interesting to say that out of the "dozen patients on radium water at any one time" of the foregoing physical therapist I have had two cases of radium poisoning —Mr. Byers and one other, in which death occurred in September, previous to the death of Mr. Byers. The second patient was brought to me the same time that Mr. Byers was and to the best of my information they took the medicine on recommendation from the same source. Both were radioactive.

"Radithor by my own tests contained 2 micrograms of radioactive material in solution. This test was made on five bottles which Mr. Byers gave me on his second visit and which he said was the preparation he had been taking. It contained both radium and mesothorium chlorides. Radium chloride can be bought for around 20 cents per microgram, mesothorium at a slightly lower price. Radium itself is quoted at $70 a milligram, which makes the metal itself worth 7 cents a microgram. Expense is a trivial matter.

"Water jars lined with carnotite or uranium ore constitute a potential danger because of the possibility of such metals as vanadium, uranium or arsenic dissolving out. I have had cases which suggested such a possibility called to my attention. These salts are poisonous. I am informed that illness occurred among the miners of radium ores in Portugal. At first it was thought it was caused by the radioactivity in the water which they drank, but it was found that the radioactivity had disappeared and that the trouble was due to salts of these metals which had gone into solution.

"On account of the slight solubility of radon or niton in water as compared with some gases, it is doubtful whether it remains in the system very long. My own experiments show that in half an hour 82.5 per cent is eliminated and 97.5 in an hour and a half. At the end of from four to five hours the expired breath is negative. Tests on persons who have drunk water for a year containing more than 2,000 mache units show at the most the mere trace of any radioactivity. These tests are not completed but will be in the near future, when the results will be reported.

"Radon is toxic to some extent. The emanations from a gram of radium bromide will kill mice in two days. Deaths have been reported when workers have been exposed to large amounts of emanation over a period of time. It will kill tissue, as tests in my own laboratory show. The advantage of radon is that the treatment can be stopped at any time by the physician and the exposure ceases. However, there is need of well controlled experiments to show definitely the value of its use. It should never be taken except under the advice of a physician who is qualified by his knowledge of physics to administer it."

In spite of many years of trial, acceptable evidence for the value of the internal use of radium solutions or of water containing radon has not become available, and until such evidence does become available the Council on Pharmacy and Chemistry has decided not to accept generators for the production of water charged with radon.

## TREATMENT OF HEMORRHOIDS

*To the Editor:*—A patient has acute prolapsed internal hemorrhoids with strangulation by a reflexly contracted sphincter accompanied by prolapse of the mucous membrane of the anus. To obtain reduction I used alternately the application of cold and a solution of epinephrine hydrochloride and chlorbutanol. Thirty-six hours after, and though the reduction was easily made, the internal hemorrhoid with the mucous membrane of the anus prolapsed again. As I examined the patient I discovered there was an inflammation of the mucous membrane of the rectum and advised my patient to undergo an operation to avoid possible disastrous consequences. He complied with my advice and was operated on. Some friend or parent of the patient called on him at the hospital and said that he had the same trouble and was cured by application of hot compresses without operation. My patient, believing him, blames me, saying that if I applied hot compresses instead of cold and epinephrine, the operation could have been avoided. The surgeon who made the operation cut off four inches of the diseased portion, more than he believed when he first examined him. I should like to have your opinion in the matter, whether I was right in the application of cold and epinephrine with chlorbutanol and recommending an operation; or could the application of hot compresses make the operation unnecessary. I will appreciate a prompt answer. Please omit name.

M.D., New York.

Answer.—The advising of cold applications and epinephri and chlorbutanol locally, and eventually an operation, was fo the best interests of the patient and therefore proper advice. I is true that occasionally thrombotic hemorrhoids will recede by expectant treatment, but by far the best treatment is to remove the clot, which offers the patient the safest and speediest convalescence.

## HYALINE CASTS

*To the Editor:*—There seems to be a considerable lack of agreement on the part of the home office examiners of certain insurance companies, on the one hand, and of the general profession, on the other, concerning the significance of hyaline casts in the urine. Assuming that, in a given case, albumin is not present, there is good concentration, and other clinical and laboratory examinations give negative results, but that occasional or even frequent centrifugated specimens of urine show hyaline casts in no large numbers, a discussion in your careful way as to their prognostic significance might be of wide interest. Such a discussion or reference to similar discussions in previous issues of The Journal will be highly appreciated.

Charles H. Stoddard, M.D., Milwaukee.

Answer.—Between better informed members of the profession and similar home office insurance men there is no disagreement concerning the significance of hyaline casts. Both will look for some reasonable explanation in any apparently healthy case with normal clinical and laboratory observations, including good concentration when casts are found frequently and in no large numbers, as the inquiry puts it.

If the patient is middle-aged or older, and especially if actively engaged, both will incline to follow Osler and look on the casts somewhat in the same way as gray hairs. If the patient is younger, they will look for strains or exposures to explain the meaning of the casts. Thus, one young man dolled himself into a rosy condition for insurance examinations, which had to be repeated because of the finding of casts, by working in a gymnasium and taking a cold plunge before furnishing specimens of urine. Another always found it more convenient to furnish specimens on his return to work just after bicycling four miles to eat a hurried dinner and do chores about the house. Still another went light on lunch so as to have an appetite for dinner, and all of the specimens he passed just before eating were acid and contained acetone as well as casts. A wide variety of similar instances, including prohibition liquor, might be cited to illustrate the advisability of seeking a reasonable explanation for the casts in such cases as those referred to.

Such cases offer an ideal field for applying the principles of preclinical medicine or the promotion of longevity because it is well known that frequent strains or malfunctions extending over long periods tend to lead to organic changes. Thus, the assumption that habits which are perfectly harmless for some may be harmful to others is borne out by insurance experience, which indicates that casts in protein-free urine are apparently without effect on mortality statistics until after a lapse of ten years or more.

Taking all ages together, it is interesting to note that insurance experience fails to show any difference in significance as between hyaline and granular casts, although fewer granular casts are expected in younger persons; also that the exhibition of casts, intermittently or constantly, does not give an unfavorable insurance experience when the cases are known to be uncomplicated. When there are complications, the picture naturally changes immediately to another, which depends on the nature of the complication.

Quantitative microscopy, which takes no more time or trouble than far less informatory methods, and sufficiently sensitive urine tests also tend to diminish disagreements because they help to clarify cases with doubtful urinary manifestations. When practitioners are in possession of information which home office insurance men do not have, or vice versa, disagreements are, of course, likely to occur, which are more apparent than real.

## TUBERCULOSIS OF KIDNEY

*To the Editor:*—1. What is the prognosis following the positive diagnosis of tuberculous kidney? 2. The frequency of spontaneous recovery? 3. What characterizes the terminal stage? 4. A positive bacteriologic diagnosis of right tuberculous kidney was made over six years ago. At present, roentgen examination shows extensive calcification of the pelvis and ureter. The phenolsulphonphthalein test shows function about one-fourth normal. Cystoscopy shows ulceration of the right ureteral orifice and the trigon of the bladder. Bacteriologic examination of the urine from the right kidney and bladder is positive for tuberculosis. The only positive observation on the left kidney is irritation of the ureteral orifice. What is the probability of involvement of the left kidney? Please discuss the advisability of surgical removal of the right kidney and the prognosis with or without surgery. M.D., Calif.

Answer.—1. The prognosis in cases of renal tuberculosis is good in cases that are treated by nephrectomy. However, bladder symptoms may persist after the kidney has been removed, and the duration of the bladder symptoms after the nephrectomy is dependent on the duration of the disease before the nephrectomy was done. In the largest number of cases, especially the early ones, the bladder symptoms completely disappear.

2. Spontaneous recovery rarely, if ever, occurs. It is doubtful whether there are any proved cases of healed renal tuberculosis.

3. The terminal stage is often marked by frequent and painful urination, hematuria, great urgency, and incontinence. The causes of death are tuberculosis of the lung, tuberculosis in the opposite kidney, tuberculous meningitis, miliary tuberculosis, and occasionally nephritis in the remaining kidney.

4. The only way to answer the question relative to the possibility of involvement of the left, or opposite, kidney is by means of ureteral catheterization, with careful bacteriologic study of the urine for tubercle bacilli. This may be done by direct smear or by guinea-pig inoculation. Intravenous pelography may be done as an adjunct, and finally, if indicated, a retrograde pyelogram. In this case nephrectomy may be done. The prognosis with surgery is good; without surgery, bad.

## ELECTROPHORESIS AS MEASURE OF VIRULENCE

*To the Editor:*—I should like to know something about the value of the Falk electrophoretic method of measuring the virulence of diphtheria bacilli. Is this just an experiment or has it really proved to be of value?

E. M. Lucke, M.D., Hannibal, Mo.

Answer.—The published evidence is conflicting. Stone and Weigel (*Am. J. Pub. Health* **19:**1133 [Oct.] 1929), who tested eighty-seven pure cultures of the diphtheria bacillus by the electrophoretic method of Falk and his co-workers and by animal inoculations, believed that their results demonstrated "the impracticability of applying the test to routine public health control practice." On the other hand, R. L. Thompson (*Am. J. Hyg.* **14:**235 [Sept.] 1931) found in a study of 173 cultures "belonging to the diphtheria group of organisms" that toxigenic and nontoxigenic cultures could generally be separated by the method of electrophoresis, the toxigenic organism migrating more slowly than the nontoxigenic. Thompson also found, however, that, contrary to the results of Jacobson and Falk, no relation existed between the virulence of a pneumococcus strain for white mice and the electrophoretic rate of migration for that strain. Obviously a method that gives diverse results in the hands of different experimenters should be adopted cautiously, if at all, as a decisive routine diagnostic test in a public health laboratory.

## IRRITANTS AND GASES AFFECTING WORKERS IN SILO

*To the Editor:*—From four to eight hours after working in a silo, a farm laborer has been troubled by coughing, headache, aching joints and subjective sensations of fever. These are not the usual symptoms of either carbon dioxide or carbon monoxide poisoning. I should be glad to know what gases are generated in a silo and whether there are cases of a fatal result. The symptoms referred to last with lessening severity for a day or two. W. J. LeRossignol, M.D., Denver.

Answer.—The prime harmful gas associated with the storage of ensilage is carbon dioxide. This gas may exist in quantities up to 75 per cent of the atmosphere, the remainder being made up almost entirely of nitrogen. Such a combination will not support life. Isolated instances of fatalities occur from time to time, but the most complete presentation of the problem may be found in an article by Mayhurst and Scott (The Journal, Oct. 31, 1914, p. 1570) reporting four fatal cases.

Carbon dioxide is not an intoxicant. As best known, it acts solely through its displacement of oxygen. In silos its abnormally high percentage is limited to the immediate time of filling with ensilage and it rapidly diminishes thereafter, so that at the end of two or three weeks no large quantity is present.

While carbon dioxide is not an irritant gas, there is associated with it an irritant, which is described by Hayhurst and Scott as "startling, pungent, alcohol-smelling, which irritates the mucous membranes and throat considerably." It is probable that this irritant is a combination of such volatile ingredients as butyric, propionic, acetic and lactic acid. The fluid that settles to the bottom of the silo contains, after fermentation, between 2 and 3 per cent of alcohol. Intoxication has been attributed to the drinking of this fluid as a beverage.

Of the case cited in the query it is believed that the manifestations may fully be accounted for on one or more of these assumptions:

(*a*) The condition may be low grade respiratory irritation from volatile acids.

(*b*) It may be allergic, following sensitization due to exposure to protein-containing dusts.

(*c*) Mechanical irritation by ensilage dusts may have inaugurated bacterial action along the respiratory tract.

Many forms of ensilage are well known, ranging from alfalfa to sunflower. It is probable that particular forms of ensilage may contain peculiar irritants, such as arise from oxidized sunflower seed oil.

## PITUITARY DEFICIENCIES

*To the Editor:*—Will you kindly outline the management of the various pituitary disorders from an endocrine standpoint, particularly in regard to glandular and radiation therapy? Recently a man, aged 31, came to me complaining of weakness, insomnia, recent increase of weight from 180 to 200 pounds (81.6 to 90.7 Kg.), and loss of mental acuity and capacity for sustained effort in the profession of law. The libido is decreased, and sexual congress increases mental apathy and leaves the patient depressed and irritable. Physical exertion quickly brings on fatigue and predisposes to infections of the upper respiratory tract. The latter are common. There are no marital, business or social conflicts. There have been two children, aged 4 and 1, both girls, who are living. The cardinal points in the physical examination are as follows: height, 5 feet 11 inches (180 cm.); weight, 200 pounds (90.7 Kg.); dilated left pupil; otherwise, reflexes normal, with vision 18/20 in the right eye and 14/20 in the left, corrected to 20/20 with glasses; thick, coarse, graying brown hair, with large, coarse eyebrows; left ethmoiditis; prominent nasal bones and hat size 7½. The thyroid is slightly enlarged and soft; the collar size is 16. There is a definite increase in collar fat pads and pelvic girdle fat. The breasts are quite large. The pulse ranges from 60 to 64; the blood pressure is 132 systolic and 80 diastolic. The abdomen is slightly obese. The testicles are about 50 per cent reduced in size and somewhat increased in firmness. The hands are large and well formed, size 8½; the feet are equally large, a size 11 B shoe being necessary. Two basal metabolic tests were done giving —18 on each occasion. The Kahn reaction is negative. A test of the spinal fluid was not done. The sella turcica is larger than normal. The patient has had a persistent tinea infection of the feet, the right hand and the scalp for the past four years. Recently an initial attack of pityriasis rosea appeared and is now receding. Headaches are rare and appear only during exacerbations of the respiratory infections. Soreness of both eyes is a marked symptom. Anything you can suggest will be greatly appreciated. Please omit name. M.D., Philadelphia.

Answer.—It is not possible, in this space, to outline fully the management of the various pituitary disorders. It may be said briefly that for the so-called hypopituitary states either low dosage roentgen therapy, applied to bitemporal fields 5 x 5 cm., or pituitary preparations subcutaneously, may be used. Pituitary tumors, of course, are treated either by surgical removal or by destructive doses of the x-rays.

Judging from the complaints of the patient, and from his size and build, the mammary development, testicular atrophy, loss of libido, lack of physical and mental endurance, the gain in weight and the prominent eyebrows, it seems that he probably has had a hyperpituitarism, particularly of the anterior lobe, which has now regressed to the hypo state, which involves both lobes. In the way of clinching this diagnosis, one should know the results of a differential blood count, a determination of the visual fields, and the blood nonprotein nitrogen, uric acid and dextrose tolerance. The presence of eosinophilia, an increased sugar tolerance and high uric acid, together with contraction of the form and color fields, would speak for a hypopituitarism. The low basal metabolic rate suggests an involvement also of the thyroid.

In treatment, solution of pituitary and of anterior pituitary should be given subcutaneously to the point of tolerance and the dose should be repeated three times a week, wholly experimentally. The anterior pituitary preparation should be kept below the amount which produces a headache and the pituitary solution should be given in doses just short of those sufficient to produce intestinal cramps.

### IMMUNITY AFTER TOXIN-ANTITOXIN IMMUNIZATION

*To the Editor:*—How long does one have immunity following the regular triple injection of toxin-antitoxin for diphtheria? Some texts seem to imply about six years and others do not state definitely.

E. C. Herber, M.A., Carlisle, Pa.

Answer.—The experience of Park and Schroder (*Am. J. Pub. Health* **18:**1455 [Dec.] 1928) is in line with that of most observers. Twenty-five infants and young children who were positive to the Schick test in 1919, and who received two injections of toxin-antitoxin when retested in 1926, gave negative reactions in twenty-three tests, a positive reaction in one and a doubtful reaction in one. Either 92 or 96 per cent retained their immunity. They also made observations on seventy-eight adults, originally giving a positive Schick test, who became negative in 1920 after one or two series of injections of toxin-antitoxin. Retested in 1928, at least 75 per cent had retained their immunity. They conclude that lapses are not great enough to make it necessary to reinject or retest as a public health measure, and that children seem to hold their immunity somewhat better than adults. They give the wise warning, however, that in time of exposure there is never certainty that a person's immunity has persisted. It must be remembered that immunity does not always result from the triple injection of toxin-antitoxin, and that this can be determined only by a subsequent Schick test.

### SUBUNGUAL EXOSTOSIS

*To the Editor:*—A man, aged 60, a shoe cobbler, noticed about four months ago a horny growth forming under his left thumb nail. It is as hard as bone, cavernous, and slightly darker than the nail. The growth has gradually increased in thickness until now it is about one-fourth inch in thickness. Three months ago a similar condition appeared under the right thumb nail and now his left great toe nail is becoming involved. The growth pushes the nail upward to such an extent that the pressure from his shoe causes pain. What is this condition? Please state cause and suggest treatment. Please omit name.

M.D., Missouri.

Answer.—This condition may be that rare type of subungual lesion discussed by L. W. Shaffer (Subungual Exostoses, *Arch. Dermat. & Syph.* **24:**371 [Sept.] 1931), who believes that these abnormalities arise from cartilaginous rests. "As the cartilaginous bud develops, it grows upward, seemingly as a branch from the phalanx; this bud, when it becomes completely osseous in a typical mature specimen, consists externally of dense cortex and internally of trabecular structure, both of which are directly continuous with the corresponding structures of the phalanx." Contrary to this concept is the fact that the lesions described by Shaffer are almost invariably limited to the great toes. Also these lesions commonly occur early in life and before 50. Trauma is mentioned as an important factor which may in this case be significant, since in a cobbler much pressure trauma arises from the hand sewing of shoes and in other shoe repairing operations. These tumors are benign and are to be accepted as teratologic anomalies rather than neoplastic. Simple paring is not efficacious; recurrences are likely to follow. Total excision is the best method of treatment, without, however, injury of the matrix. Details of the operative procedure are furnished in the article cited. Roentgen examination, except in very early cases, will establish the condition as an exostosis if such is the case. If not, consideration must be given to the possibility of granuloma pyogenicum, warts, simple fibroma, and a malignant condition.

Alabama: Montgomery, July 11. Sec., Dr. J. N. Baker, 519 Dexter Ave., Montgomery.

American Board for Ophthalmic Examinations: Montreal, Sept. 19. Sec., Dr. William H. Wilder, 122 S. Michigan Ave., Chicago.

American Board of Otolaryngology: Montreal, Sept. 17. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

Arizona: Phoenix, July 5-6. Sec., Dr. B. M. Berger, 12 North Central Ave., Phoenix.

California: San Francisco, July 11-14. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

Colorado: Denver, July 5. Sec., Dr. Wm. Whitridge Williams, 422 State Office Bldg., Denver.

Connecticut: *Regular.* Hartford, July 12-13. *Endorsement.* July 26. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Homeopathic.* New Haven, July 12. Sec., Dr. Edwin C. M. Hall, 82 Grand Ave., New Haven.

District of Columbia: Washington, July 11-12. Sec., Dr. W. C. Fowler, 203 District Bldg., Washington.

Hawaii: Honolulu, July 11-14. Sec., Dr. James A. Morgan, Room 48 Young Bldg., Honolulu.

Maine: Augusta, July 5-6. Sec., Dr. Adam P. Leighton, Jr., 192 State St., Portland.

Massachusetts: Boston, July 12-14. Sec., Dr. Stephen Rushmore, 144 State House, Boston.

North Dakota: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, Grand Forks.

Oregon: Portland, July 5-7. Sec., Dr. C. J. McCusker, 1014 Medical Dental Bldg., Portland.

Pennsylvania: Philadelphia and Pittsburgh, July 5-9. Sec., Mr. Charles D. Koch, Dept. of Public Instruction, Harrisburg.

Rhode Island: Providence, July 7-8. Dir., Dr. Lester A. Round, 319 State Office Bldg., Providence.

South Dakota: Waubay, July 19. Dir., Dr. H. R. Kenaston, Bonesteel.

Utah: Salt Lake City, July 6-8. Dir., Mr. S. W. Golding, 326 State Capitol Bldg., Salt Lake City.

Washington: *Basic Science.* Seattle, July 7-8. *Regular.* Seattle, July 11-12. Dir., Mr. Charles Maybury, Olympia.

West Virginia: Harpers Ferry, July 12. Sec., Dr. W. T. Henshaw, State Health Dept., Charleston.

## Colorado April Report

Dr. William Whitridge Williams, secretary, Colorado Bo of Medical Examiners, reports the written examination Denver, April 6-9, 1932. The examination covered 8 s and included 80 questions. An average of 75 per ce required to pass. Three candidates were examined, all of passed. Four physicians were licensed by endorsement. following colleges were represented:

| College | PASSED | Year Grad. | |
|---|---|---|---|
| University of Colorado School of Medicine | | (1931) | 8 |
| Rush Medical College | | (1932) | 9 |
| Osteopath | | | 7. |

| College | LICENSED BY ENDORSEMENT | Year Grad. | Endorsem of |
|---|---|---|---|
| College of Medical Evangelists | | (1931) | Californ |
| Rush Medical College | | (1929) | Illinc |
| Indiana University School of Medicine | | (1925) | Indian |
| Washington University School of Medicine | | (1925) | Missour |

## California Reciprocity Report

Dr. Charles B. Pinkham, secretary, California Board of Medical Examiners, reports 58 physicians licensed by reciprocity with other states and 5 physicians licensed by endorsement from Jan. 2 to April 14, 1932. The following colleges were represented:

| College | LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|---|
| University of Arkansas School of Medicine | | (1930) | Arkansas |
| University of Colorado School of Medicine | | (1917), (1930) | Colorado, (1922) Virginia |
| Emory University School of Medicine | | (1926) | Georgia |
| Southern Medical College, Georgia | | (1893) | Colorado |
| Chicago Medical College | | (1888), (1894) | Illinois |
| Coll. of Phys. and Surgs. of Chicago | | (1892), (1894), (1911) | Illinois |
| Hahnemann Medical College and Hospital, Chicago | | (1920) | Illinois |
| Northwestern University Medical School | | (1923) | Utah |
| Rush Medical College | | (1895), (1919) Iowa, (1910) | Utah, (1901), (1911, 2), (1929, 2) Illinois |
| University of Illinois College of Medicine | | (1916) | Illinois |
| Indiana University School of Medicine | | (1911) | Indiana |
| State University of Iowa College of Med. | | (1897), (1927) | Iowa |
| University of Kansas School of Medicine | | (1922) | Montana |
| Tulane University of Louisiana School of Medicine | | (1924) | Louisiana |
| Baltimore Medical College | | (1890) | Maryland |
| Harvard University Medical School | | (1921) | Utah |
| University of Minnesota Medical School | | (1922), (1925) | Minnesota |
| Ensworth Medical College, Missouri | | (1913) | Missouri |

| | | |
|---|---|---|

| University of Pennsylvania School of Med. | (1919), (1926) | N. B. M. Ex. |

## Montana April Report

Dr. S. A. Cooney, secretary, Montana State Board of Medical Examiners, reports 6 physicians licensed by reciprocity with other states, April 15, 1932. The following colleges were represented:

| College — LICENSED BY RECIPROCITY | Year Grad. | Reciprocity with |
|---|---|---|
| Northwestern University Medical School | (1930) | California |
| University of Minnesota Medical School | (1930, 2) | Minnesota |
| University of Nebraska College of Medicine | (1925, 2) | Nebraska |
| University of Oregon Medical School | (1930) | Washington |

# Book Notices

**The Human Voice: Its Care and Development.** By Leon Felderman, M.D. Cloth. Price, $2.50. Pp. 301, with 22 illustrations. New York: Henry Holt & Company, 1931.

Either directly or indirectly, many organic and psychologic factors, including disease, are capable of influencing the complicated and difficult function of artistic voice production, particularly singing. The author conceives that all these factors should be comprehended and information concerning them placed at the disposal of the vocalist and vocal trainer. The theme is both important and ambitious. In each of most of the forty-eight chapters, some disease or other organic or psychologic factor supposedly bearing on artistic voice production is discussed. For the most part the subjects treated refer to the air passages directly, for example, "laryngitis" and "nervous disorders of the pharynx"; but other chapters discuss more indirect subjects, such as "headache," "alcohol," "immunity from disease," and "goiter." Obviously the basis on which such discussions should rest is a clear analysis of the speech mechanism itself and the psychologic and physiologic principles involved in its employment for the purposes of singing; but the author's descriptions on these subjects (including also the illustrations) are largely vague and inadequate. Owing in part to the failure to build such foundations strongly, the relation of disease or other factors discussed to the function of singing is usually not clearly depicted. The chapters vary greatly in value. Generally speaking, the text lacks in clear analysis of its subjects, being somewhat sketchily presented. One comes to question the author's opinions. For example, without discussing especial individual susceptibility to the inhaled drugs of tobacco, or the significance of "inhaling" the smoke, or the possible irritative effects of tobacco on the mucous membranes, the author expresses the opinion, possibly fraught with danger, that tobacco is essentially harmless to the singer. The chapter on the anomalies of speech is especially confused and inadequate. Analysis of tonsillectomy from the point of view of the singer, a subject that especially needs clarification, is omitted. While the vocalist will find much of interest and value in this volume, its real significance lies in the initiation of a unique and valuable subject for book making. It is to be hoped that a future edition will appear with important revisions of the present text.

**La maladie de Boeck: Sarcoïdes cutanées bénignes multiples.** Par le Docteur A. Kissmeyer, médecin de l'Institut Finsen. Préface du Dr. J. Darier. Paper. Pp. 147, with 67 illustrations. Copenhagen: Levin & Munksgaard, 1932.

This is a monograph of real value, covering a phase of cutaneous medicine which has caused a great deal of discussion among dermatologists. In the preface, Darier highly congratulates the author on his work but shrewdly urges further research before entirely discarding the theory of a tuberculous causation. The introduction presents the historical background of the controversy over sarcoids. Following this is a clinical and histologic description of the various types of cutaneous sarcoid and of the involvement of the eye, mucous membranes, lymph nodes, lungs, muscles, internal organs and the bones. Special emphasis is placed on lung involvement. The chapter on etiology and pathogenesis discusses the theory of a tuberculous etiology of sarcoids from every possible angle, with the conclusion that the disease is not caused by the bacillus of Koch. The author compares the histologic appearance of sarcoid with that of leprosy, especially as it occurs in the osseous system. Prognosis and treatment are then discussed. The conclusion of the author is that this condition belongs among infective granulomas of unknown etiology; but histiogenetically he places it between tuberculosis and leprosy. The true worth of the illustrations has been lost because of the poor quality of paper used.

**Nudism Comes to America.** By Frances and Mason Merrill. Cloth. Price, $3. Pp. 300, with illustrations. New York: Alfred A. Knopf, 1932.

It remains for the psychologist to explain the nudist movement. From the standpoint of health there is no reason to believe that exposure of the entire body to sunlight and fresh air will accomplish any more than exposure of those portions of the body that do not shock the puritanical. The authors of this book have visited the nudists in their special assemblages abroad and in this country. They present a complete survey of the extent to which organized nudism has made its appearance among us. One chapter is entitled "What Physicians Think." In this chapter the authors have collected replies to a questionnaire, statements from the literature, quotations from magazines and newspapers and other material from all sorts of sources. They do not, of course, distinguish between competent scientific opinion and notions. The illustrations chosen for the book are photographs of nudism in action, but neither the female nor the male reproductions of nudism in the book are in general nearly as repulsive as most of the actual nudists when seen in their colonies. These pictures seem to have been chosen for the beauty of the models rather than for demonstration of conditions as they are.

**Ernährung und Diät bei Tuberkulose.** Von Dr. Med. Paul Rehfeldt, Polizei-Medizinalrat in Köln a. Rh. Unter Mitwirkung von Professor Dr. med. Adolf Bacmeister, leitender Arzt des Sanatoriums für Lungenkranke in St. Blasien. Paper. Price, 13.50 marks. Pp. 187. Dresden: Theodor Steinkopff, 1932.

In an introduction to this complete work, Bacmeister writes that the surgical treatment of pulmonary tuberculosis in recent years has made such strides that it has overshadowed dietetic considerations, and tuberculosis as a general disease has been neglected. The ideas of Sauerbruch, Herrmannsdorfer and Gerson restored interest in dietetic treatment. Their treatment has been successful in skin and bone tuberculosis but disappointing in the treatment of pulmonary tuberculosis. The book is divided into nine interesting chapters, beginning with metabolism in tuberculous patients. The Harris-Benedict tables are given in regard to caloric needs, and the variations from the normal in tuberculous patients are discussed in regard to the various foodstuffs. The concept of a demineralized body in tuberculosis is not accepted, but, in contrast with the healthy, the tissues have not the same capacity to fix the mineral salts. The relationships of the different minerals and the different vitamins to general immunity are fully discussed. The absence of a single vitamin in the diet favors the progress of tuberculosis. Scientific investigation has reestablished the value of cod liver oil. The relationship of constitution to tuberculosis is sketched from Hippocrates and Hufeland to the present time. Inherited constitution is influenced by climate, nourishment, training, work and illness. Tables are given to illustrate the proper growth of children and the correct weights of adolescents. The three main types of Kretschmer, in regard to body form, are analyzed, the asthenic or narrow chested, the thick chested, and the athletic types. In puberty the proportion of tuberculous patients is highest in the asthenic type, and in this type there is less ability to develop immune bodies and to form connective tissue. The thick-chested type of individual has greater reaction power of the tissues to infection but is more prone to gout, arteriosclerosis and other constitutional diseases. This type has a better chance of overcoming tuberculosis. These constitutional types are discussed in relation to treatment such as climate, occupational therapy, and diet. Extensive dietetic tables are given with the balanced proportions of albumin, fat, carbohydrate and their resultant calories, and also depicting the mineral content of different foods. A body weakened by lack of food has an increased sensitiveness and a lessened resistance to tuberculosis. The central nations, impoverished in food during the World War, showed an astonishing increase in tuberculosis mortality. "Hunger is the reminder, appetite is the desire for food," and the art of diet and medication is described for the tuberculous in whom toxic conditions destroy appetite. The salt-free diet of Herrmannsdorfer is fully discussed and its advantages pointed out in skin, bone and joint tuberculosis, and in tuberculous fistulas. In pulmonary tuberculosis the addition to the diet of vitamin-containing vegetables and fruits, of cod liver oil and of calcium is stressed. Excellent results were seen in patients who could take daily six oranges, two raw egg yolks, a teaspoonful of cod liver oil after each meal, and a calcium preparation half an hour before each meal. The employment of insulin in diabetic patients is outlined, and tables of diet for these patients are given. The advantage of insulin for stimulating the gain in weight and well being of the nondiabetic tuberculous patient is pointed out. The dietetic treatment of intestinal and renal tuberculosis is fully discussed and also the dietetic treatment of nephritic complications. The book is thoroughly modern in the physiology of nutrition and represents a valuable contribution to the library of those engaged in tuberculosis work.

**Man and Microbes.** By Stanhope Bayne-Jones, M.D., Professor of Bacteriology, School of Medicine and Dentistry, University of Rochester, Rochester, New York. Cloth Price, $1. Pp. 128, with 16 illustrations. Baltimore: Williams & Wilkins Company, 1932.

This little volume is a part of a series to be issued in connection with the Century of Progress Exposition in Chicago. The books are planned to make understandable the advance of science. It is doubtful whether any better performance could have been made as a contribution to this series than this book by the professor of bacteriology at the University of Rochester. He makes clear the place of discoveries in technic as the basis of advance in the science of bacteriology; he has a feeling for historical background, and he provides a vast number of facts of importance for the prevention of disease. The book is beautifully illustrated, well written and an exceedingly worthy contribution to the series.

**Ergebnisse der Enzymforschung.** Herausgegeben von F. F. Nord und R. Weidenhagen. Band I. Cloth. Price, 29 marks. Pp. 377, with 63 illustrations. Leipzig: Akademische Verlagsgesellschaft m.b.H., 1932.

The realm of enzyme research involves problems concerned alike with chemistry and with physiology and serves to establish a closer relationship between these two branches of science. For this reason the literature of enzyme studies is found widely scattered in natural science and medical publications. In order to offer a survey of material which is not easily accessible, the plan was developed to publish from time to time a collection of summarizing reports on various topics of enzyme research. The papers are designed not to be comprehensive reviews of the literature but rather to deal with special problems and particularly to present the writers' own work in the field. This volume is therefore the first of a series, which will appear at intervals in the future. The book includes an elaborate author index. References to the literature are given for all work discussed or mentioned. The summaries vary in length from six to forty pages, the average being approximately twenty pages. The material is presented in the language native to the author of the discussion; and the book therefore contains reviews written in English, French and German. The men chosen to present various phases of enzyme research are leaders in their respective fields and have aided in preparing an excellent book, which should be of value to those interested in the chemistry and the physiology of enzymes. The table of contents includes articles covering the thermodynamics of cell reactions, significance of oxidation-reduction potentials in enzymatic reactions, mechanism of enzyme action, physical chemical processes in enzyme reactions, alcoholic fermentation, proteolytic enzymes of the plant and animal world, specificity and mode of action of carbohydrates, bacterial enzyme reactions, acetic fermentation, tyrosinase, bone phosphatase, crystalline urease, crystalline pepsin, the oxygen transporting ferment of respiration, biochemistry of the lower fungi, and the activation of plant enzymes.

***Hépatites et cirrhoses: Classification, pathogénèse et morphogénèse des hépatites diffuses aiguës, subaiguës et chroniques d'après les notions récentes sur la physiopathologie hépato-biliaire.*** Par Guy Albot. Préface du Pr. G. Roussy. Paper. Price, 34 francs. Pp. 247, with 56 illustrations. Paris: Masson & Cie, 1931.

The first part of this book on some of the common diseases of the liver deals with experimental data showing the evolution of acute diffuse hepatitis to more chronic forms. The second part is devoted to a scholarly discussion of anatomicoclinical material in which the experimental observations seem to be duplicated and the transition of hepatitis is traced to chronic forms and eventually to cirrhosis. It is emphasized that cirrhosis is a form of chronic inflammation of the liver, slow in development but involving all the elements of the liver lobule. The author describes in great detail the various pathologic and histologic changes, many of which are well illustrated by photomicrographs and by drawings. Much of the material represents personal experimental and anatomic study. The author's own observations are woven with the work of others into an interesting and compact discussion of the various forms of hepatitis and cirrhosis. Briefly, diffuse hepatitis is divided into three large groups: toxiinfectious, the hepatitis of biliary stasis, and the form associated with passive congestion. Transitional stages are described, linking the acute with the chronic forms and the latter with cirrhosis. It is stated that not all cases progress to the stage of cirrhosis but that some may stop at earlier periods in development. There then follows a copious list of protocols taken from anatomic and experimental studies. A good bibliography and a summary of the author's conclusions are found at the end.

**The Aetiology of Tuberculosis.** By Dr. Robert Koch. A translation from the German of the original paper announcing the discovery of the tubercle bacillus, read before the Physiological Society in Berlin, March 24, 1882, and published in the Berliner Klinische Wochenschrift, 1882, XIX, 221, specially prepared for The American Review of Tuberculosis, March, 1932, by Dr. and Mrs. Max Pinner. With an introduction by Dr. Allen K. Krause. Cloth. Price, 50 cents. Pp. 48, with 8 illustrations. New York: National Tuberculosis Association, 1932.

As a memento of the fiftieth anniversary of Koch's discovery of the cause of tuberculosis, the National Tuberculosis Association has published an English translation of the original essay of Koch together with an introduction by Dr. Allen K. Krause. The book is illustrated with facsimiles of the original illustrations in the book on the subject and the contribution to the *Klinische Wochenschrift*. The price of the publication is so reasonable that it should be in the library of every worker in the field.

**Traitement de la tuberculose par la sanocrysine.** Par Knud Secher, médecin-chef à l'Hôpital de Bispebjerg, Copenhague. Paper. Pp. 110, with 21 illustrations. Copenhagen: Levin & Munksgaard; Paris: J. B. Baillière & Fils, 1932.

This small monograph represents an exposition of the author's experience and ideas concerning treatment of tuberculosis with "Sanocrysin" (gold sodium thiosulphate). The frankness with which he admits the severe reactions and results at the beginning of the experiments is to be admired, for such is the lot of the pioneer; but the rather dogmatic assertions that the "reactions" are tuberculin reactions and the insistence on the necessity of heavy "sterilizing" doses are not to be accepted without question. The author's review of the literature in support of the tuberculin-like action is biased in favor of the theory, leaving out any reference to the excellent work of the Japanese and others, who found no proof of such a tuberculin reaction in animals. Although there may be and perhaps is a certain degree of such action, many of the reactions resemble metallic poisoning, such, for example as salivation, severe pain and exfoliative dermatitis following large doses. As to the "sterilization" of tuberculous lesions, there is little established evidence of a direct effect on the tubercle bacilli. The opinion is now generally in favor of an indirect action on the body rather than a direct one on the parasites. Patients with disseminated bacilli without resistance are not affected at all favorably, which indicates a lack of bactericidal effect. There is therefore no need to adhere to the large and rather dangerous dosage advocated by the author. On the other hand, good results have been obtained by many others, without the objectionable reactions, by using smaller dosage. The indications, contraindications, types of reaction and various systems of dosage are rather well given and are useful as guides in treatment. The methods of dosage used by Permin and especially by Sayé afford a good plan to all those contemplating use of the drug. In the evaluation of the results of treatment, several authors are cited, but perhaps the most representative is that of Stub-Christiansen, who showed that 53 per cent of treated patients are able to work after one year, while only 37 per cent remain in that condition after five years. With certain reservations regarding the author's method of dosage, the booklet may be used as a guide in treatment with "Sanocrysin."

**Walter Bradford Cannon: Exercises Celebrating Twenty-Five Years as George Higginson Professor of Physiology, October 15, 1931.** Boards. Pp. 94. Cambridge: Harvard University Press, 1932.

In connection with the presentation of the portrait of Dr. Walter B. Cannon to Harvard and the celebration of his twenty-five years of service as professor of physiology, a beautiful souvenir volume has been issued. It includes the addresses made on the important day by Drs. Edsall, Alvarez, Howell and Lusk, the acceptance address of President Lowell, and a record of Dr. Cannon's service, together with a bibliography of his writings. The book is beautifully printed, contains a reproduction of the portrait, and will be appreciated by all those who know Dr. Cannon.

**Gynäkologische Operationslehre.** Von Hofrat Prof. Dr. Josef Halban. Paper. Price, 37.50 marks. Pp. 448, with 398 illustrations. Berlin: Urban & Schwarzenberg, 1932.

The author's aim in this book is to accomplish two purposes: to describe the technic of gynecologic operations and to point out the indications for these operations. As Halban emphasizes, it is frequently more difficult to know whether and when to operate than how to perform an operation. The purposes have been so well fulfilled that this book is one of the best books on surgical indications and technic ever published in any language. Because there are numerous different operations for many gynecologic conditions, Halban describes and illustrates the ones which he himself generally performs. For this reason the book is most valuable. There are few gynecologists in the world who can equal Halban's ability to perform vaginal operations. It is unfortunate that the large majority of gynecologists in this country, especially the younger ones, are unfamiliar with the technic of vaginal operations. The latter operations have a decidedly lower mortality and morbidity than laparotomies, and all gynecologists should learn the anatomy and technic of vaginal operations in order to give their patients the benefits of these operations. The author describes not only gynecologic operations but also operations on the bladder, ureter and kidney, the repair of hernias and the removal of the appendix, hemorrhoids and pulmonary emboli. The illustrations cannot be surpassed for their accuracy, clearness and instructiveness. Every gynecologist should obtain a copy of this book, even those who cannot read German, for there are enough illustrations to label this book an excellent atlas.

**The Business Man and His Health.** By Jesse Feiring Williams, M.D. Cloth. Price, $2. Pp. 175. New York and London: McGraw-Hill Book Company, Inc., 1932.

Dr. Williams has planned this book for people who work indoors. It is a brief book of common sense advice, written in simple but somewhat prosaic form. Since people who work indoors are much like other people except for the fact that they work indoors, the book is really a good book on personal hygiene for every one. Especially to be recommended is the chapter on the choice of a physician.

# Medicolegal

## Practice of Dentistry by a Corporation

*(Parker v. Board of Dental Examiners of State of California (Calif.), 1 P. (2d) 501)*

"Painless Parker Dentist," a corporation, was organized to "conduct, own, operate and control dental offices." E. R. Parker, one of its incorporators, a licensed dentist, changed his name to "Painless" Parker, by court decree. Apparently, the corporation never acted in any respect other than to appoint Painless Parker, the incorporator named above, as its "manager and chief surgeon." The corporation never paid a dividend nor had any assets or funds on hand. Shortly after the incorporation of "Painless Parker Dentist," the Associated Dental Supply Company was organized as a corporation to deal in all kinds of dental supplies. When proceedings to revoke Painless Parker's license were instituted, fourteen dental offices seem to have been operating in California by dentists using "the E. R. Parker system," all owned or leased by the Associated Dental Supply Company, but these offices were in turn "leased" by that company to the Painless Parker Dentist corporation. Notwithstanding this subleasing of these offices, however, the Associated Dental Supply Company seems to have dealt directly with the managers of these local dental offices, and these managers deposited all the receipts of their respective offices to the credit of the Associated Dental Supply Company. Painless Parker, the individual, seems to have supervised the operation of all the offices for the benefit of the Associated Dental Supply Company. He employed a licensed dentist as the local manager of each office, and each such local manager employed licensed dentists to perform all necessary dental operations. Painless Parker Dentist, the corporation, was apparently the lessee of these offices, and the term "Painless Parker Dentist" appeared on the doors, windows and letterheads, although later the term "dentists using the E. R. Parker system" was substituted. But Painless Parker, the man, managed these offices apparently for the benefit of the Associated Dental Supply Company.

Painless Parker's conduct was deemed unprofessional by the California board of dental examiners, and after notice and hearing it revoked his license to practice dentistry. Parker petitioned the superior court, city and county of San Francisco, to set aside the revocation, which the court refused to do. He then appealed to the district court of appeal, first district, division 2, California.

Section 11, Act 2048, Deering's General Laws, 1923, the dental practice act, declares the practice of dentistry to include the activities of any one "who manages or conducts as manager, proprietor, conductor, or otherwise a place where dental operations are performed." Section 13 of that act defines as unprofessional conduct "aiding or abetting any unlicensed person to practice dentistry unlawfully." The conduct of Parker, contended the board, was "unprofessional" in that he aided and abetted an unlicensed person, the Painless Parker Dentist corporation, to practice dentistry "by permitting, allowing and authorizing said corporation to conduct, own, operate, and control dental offices throughout the state . . . where dental operations were performed, and carry on the practice of dentistry therein." The board contended that conducting, owning, operating, and controlling dental offices constituted the practice of dentistry within the purview of section 11 of the dental practice act, *supra;* that a corporation cannot be licensed to practice dentistry; and that any licensed dentist who aids a corporation in performing any of the acts named above is aiding "an unlicensed person" to practice. Parker claimed, however, that the term "unlicensed person," as used in the prohibition of "aiding and abetting any unlicensed person to practice dentistry unlawfully," refers only to natural persons, who might be licensed under the act, and not to a corporation owning or operating a dental office, and that the provisions of section 11 are unconstitutional so far as they purport to prohibit an unlicensed person from managing the purely business or economic affairs of a dental office.

Bearing in mind, said the district court of appeal, that the ultimate purpose of the dental practice act is to bring about and insure skill and proficiency in the practice of dentistry, section 11 as construed by the board would be unconstitutional, because it would place unreasonable restrictions on the conduct of a lawful business. To support this statement the court quoted from *State* v. *Brown*, 37 Wash. 97, 79 P. 635, decided in 1905. In that case the Supreme Court of Washington had under consideration a provision of the dental practice act of Washington, which made it a misdemeanor for an unlicensed person to "own, run, operate or cause to be operated, or manage a dental office." The Washington court said, in part, as follows:

> To own and manage property is a natural right, and one which may be restricted only for reasons of public policy, clearly discernible. . . . But, we are unable to say or perceive that the health, moral, or physical welfare of the public, or any of the personal or property rights of its individuals, are endangered by the ownership and management of a dental office, so long as those employed therein to do the actual dentistry work are qualified and licensed as by law required.

The Supreme Court of Washington in its exposition of the supposed unreasonableness of the Washington statute described the hypothetical case of a supposed widow of a licensed dentist, who assumed control and management of the business of the office of her deceased husband, and who, though she employed none but licensed dentists to perform the dental work, would be chargeable under the strict terms of the act with practicing dentistry without a license. Other illustrations, said the California district court of appeal, might be added. "The manager or proprietor of a place where dental operations are performed," said the court, "would include the manager and owner of every hospital and clinic permitting such operations, the many charitable agencies maintaining clinics, the infirmaries and guilds maintained and operated by the students in universities and colleges, the many dental clinics maintained by parents' organizations for the benefit of school children, as well as the owners and managers of buildings where such operations are performed."

The California court found further authority for its holding, in *Messner* v. *Board of Dental Examiners*, 87 Calif. App. 199, 262 P. 58, decided in 1927, in which the court of the third appellate district annulled an order suspending the license of a dentist on the charge that an unlicensed person was the "manager" of his office. In that case, the court said, in part, as follows:

> Cohn had charge of the purely business end of the dental office, . . . but there is no evidence that he had or exercised the slightest control or direction of the professional work performed in such office. . . . A reasonable construction of the quoted provisions of the statute appears to be that, to come within the terms thereof, one must in some manner, to some extent, directly or indirectly, control or direct some professional service of the kind that dentists are licensed to render.

The court found itself in full accord with and quoted from *State Electro-Medical Institute* v. *State*, 74 Neb. 40, 103 N. W. 1078, decided in 1905, as follows:

> There was no necessity of legislation to prohibit corporations, as such, from practicing medicine. It is impossible to conceive of an impersonal entity "judging the nature, character and symptoms of the disease," or "determining the proper remedy," or giving or prescribing the application of the remedy to the disease. Members of the corporation, or persons in its employ, might do these things, but the corporation itself is incapable to do them. The qualification of a medical practitioner is personal to himself. The intention of the law is that one who undertakes to judge the nature of a disease or to determine the proper remedy therefor, or to apply the remedy, must have certain personal qualifications; and, if he does these things without having complied with the law, he is subject to its penalties. Making contracts is not practicing medicine. Collecting the compensation therefor is not practicing medicine, within the meaning of this statute. No professional qualifications are requisite for doing these things.

It follows, said the California court, that when the California legislature declared it to be unprofessional for a licensed dentist to aid an unlicensed person to practice dentistry, it did not contemplate aid to a corporation, which itself could not become licensed under the act and which could do no more than conduct the business side of the office. Since a corporation cannot practice dentistry, Parker could not have aided it to practice and could not have been guilty of unprofessional conduct in this respect as charged by the board.

The board of dental examiners charged further that Parker had been guilty of unprofessional conduct in that he aided an unlicensed person, Ramona McShane, to practice dentistry unlawfully by permitting her to participate in the profits of the dental offices operated by "Painless Parker Dentist, a corporation." The board, to support this charge, introduced evidence that some years ago the Associate Dental Supply Company executed a trust agreement and sold trust certificates in small denominations. Ramona McShane purchased a number of these certificates, and dividends were later paid to certificate holders. As the Painless Parker Dentist corporation leased offices from the Associated Dental Supply Company, the board, after its hearing in the case, held that Ramona McShane participated in the profits of the Painless Parker Dentist corporation that she therefore practiced dentistry unlawfully, and that Painless Parker aided and abetted her in so doing. But, said the district court of appeal, it would be just as reasonable to hold that every stockholder of a bank which has lent money to the owner of a building in which some dentist has practiced without a license is an aider and abetter in the unlawful practice of dentistry. To interpret the statute as contended for by the board would make it unconstitutional for the reasons stated above. If, however, the statute is given a reasonable and constitutional interpretation, the evidence demonstrates that Ramona McShane was not practicing dentistry within any sound construction of the act.

The board held also, after its hearing, that Painless Parker had been guilty of unprofessional conduct in that he practiced under an assumed or fictitious name in the use of the term "Painless Parker Dentist." But, said the court, the name Painless Parker Dentist was not fictitious. Parker was practicing under the name given him by decree of court, which also was the name under which he was licensed to practice by the board.

For the reasons stated above, the order of the California board of dental examiners suspending Parker's license to practice dentistry was reversed.

# Society Proceedings

## COMING MEETINGS

American Ophthalmological Society, New London, Conn., June 27-29. Dr. Emory Hill, 501 East Franklin Street, Richmond, Va., Secretary.

Montana, Medical Association of, Miles City, July 13-14. Dr. E. G. Balsam, 208 North Broadway, Billings, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 27-29. Dr. Frederick Epplen, 1215 Fourth Avenue, Seattle, Secretary.

Western Branch of the American Urological Association, Portland, Ore., July 1-2. Dr. F. S. Dillingham, 548 S. Spring Street, Los Angeles, Secretary.

Wyoming State Medical Society, Rock Springs, July 18-19. Dr. Earl Whedon, 50 N. Main Street, Sheridan, Secretary.

## ASSOCIATION OF AMERICAN PHYSICIANS

*Forty-Seventh Annual Meeting, held at Atlantic City, N. J., May 3 and 4, 1932*

The President, DR. THOMAS B. FUTCHER, Philadelphia, in the Chair

### Use of the Matthews Oscillograph in Phonocardiography

DRS. WILLIAM J. KERR, JOHN J. SAMPSON, JOHN B. LAGEN and FREDERICK KELLOGG, San Francisco: The advantages of studying heart sounds by graphic means are as follows: 1. Permanent records are available for comparison. 2. Confused rhythms may be analyzed. 3. Detailed study of pitch, time and intensity of sound elements is possible. 4. Sounds normally inaudible may be recorded and studied. 5. Sounds may be analyzed from a different group of criteria in special relationship of pitch and intensity. The methods used condenser microphones and various types of rigid electroschemes, use of the Einthoven string galvanometer in series with a carbon particle or electromagnetic microphone, and the Einthoven galvanometer in series with an electron tube amplifying circuit and electrical filter, as well as an electromagnetic microphone. Recently Sell, Duchosal and others have used condenser microphones and various types of rigid electromagnetic oscillographs with natural periods higher than those of the Einthoven galvanometer with customary string lengths. Other types of oscillographs, particularly the cathode ray oscillograph and the short string Einthoven galvanometer, have been developed for other purposes and not yet applied to phonocardiography. Our purpose in this presentation is to show illustrations of the character of records taken with a Matthews electromagnetic oscillograph with a high natural period and an electrical amplifying and filtering mechanism (the Western Electric Company's IA electrical stethoscope) as transmitted from a solid medium conducting electromagnetic microphone. The results obtained are favorably comparable to the records published by any of the other methods with a recorded range from 64 to 2,048 vibrations a second. The technic is simple and rapid, with or without simultaneous electrocardiograms.

DISCUSSION

Dr. F. N. Wilson, Ann Arbor, Mich.: I should like to ask about the microphone, whether it is capable of responding accurately to vibrations of very high frequency. Some years ago Dr. H. P. Williams, working with the Western Electric Company on the electric stethoscope, thought that the record of the galvanometer as showing response to high frequencies would not be any good unless the microphone was corrected. He felt that it did not respond accurately enough to sounds of very high frequencies.

Dr. William J. Kerr, San Francisco: We have been able to reproduce tuning fork vibrations of 2,048 frequency with a fair degree of accuracy, but this tracing does not enlarge very well on the slide. Later we hope to send some of our results to Dr. Wilson for comparison.

### Vaccine Therapy in Rheumatic Cardiovascular Disease

Drs. W. D. Stroud, Albert W. Bromer and J. Roswell Gallagher, Philadelphia: These studies are based on ten years' observations in the Children's Heart Hospital in Philadelphia, which cares for children suffering from severe rheumatic cardiovascular disease. Treatment has included removal of foci of infection, removal from home environment, possible removal of familial contagious factors, care, rest and sufficient diet. The results have been disappointing. First of all, the follow-up results were unsatisfactory. Of 405 children, we have been able to follow up completely only 64 per cent. Thirty-six per cent have been lost sight of. Results in the 64 per cent were disappointing. Of these, 34 per cent died uncompensated, at the hospital or at home. Thirty per cent improved sufficiently to continue at work or at school. We knew that other workers had unsatisfactory results also and we wondered whether it would not be better to spend our funds on sending the children to Porto Rico or to Florida, rather than on research work. We were interested in Swift's work on the hyperergy of these children to streptococci, and we studied how to make them hyposensitive. We divided the children into three groups, as regards similarity of age. Twenty-five were under 17 years of age. We divided these into groups as to hypersensitivity to streptococci, and also as to the extent of cardiovascular damage and functional disability. Treatment also was grouped. Group 1 received the triple streptococcus vaccine of Swift in weekly injections; group 2 received triple typhoid vaccine; group 3 was used for control. Our method was to begin with a dose of from 50,000 to 100,000 and work gradually up to doses of 25 million. The triple typhoid vaccine could not be raised above 15 million on account of severe reactions. The visiting nurse went to the home of the patient to follow up the reactions and to fill in the questionnaire. There were more severe reactions in the triple typhoid group than in the other. Exacerbations often seemed to be delayed and were apt to appear in March. We wondered whether this could be attributed to seasonal influence. Our conclusions were that we must be very cautious in determining the results of the treatment. We feel it would be better to treat only a small group, so that each individual case can be followed up. We felt that there were no harmful results to be observed, and after consultation with Dr. Swift we feel justified in continuing the vaccine therapy. We intend to use younger individuals and to give the triple streptococcus vaccine intravenously.

DISCUSSION

Dr. Homer F. Swift, New York: In discussing this interesting report, one must realize the difficulty in evaluating the effect of any therapy in this disease, especially over such a limited period. Recently Dr. May Wilson has reanalyzed the data on the condition of the rheumatic children at the New York Nursery and Child's Hospital. In a report made before this association two years ago, a group of about 80 children vaccinated intravenously during a period of two years had a distinctly lower incidence of relapses than an unvaccinated group of similar size. Vaccination was then stopped for about two years; and recently the old vaccinated group has shown a higher incidence of recurrences than the nonvaccinated. At least two explanations of this phenomenon are applicable: 1. Relative freedom from relapses may be followed by a greater susceptibility. 2. In emerging from a condition of relative immunity, or hyposensitiveness, there may be a phase of hypersensitiveness.

### Myocardial Failure Due to Trichinosis

Drs. Carl V. Weller, Ann Arbor, Mich., and Milton Shaw, Lansing, Mich.: In 1865, Kornblum noted the occurrence of a marked parenchymatous degeneration in the heart of a patient dying of trichinosis. He found millions of trichinae in the skeletal muscle but none in the heart muscle. In the latter there was probably an active defensive process characterized by a large number of eosinophils. With one exception (Frothingham in 1906 described what he believed to be an embryo in heart muscle) there have been no reports of trichinae found in heart muscle fibers. This led to the view that there was a toxic substance found in the body which was carried through the blood stream. We have studied a patient brought to the St. Lawrence Hospital. His illness, which had lasted six weeks, commenced with diarrhea; he had fever, night sweats and muscle pains. On admission he was nearly moribund. He had dyspnea, cyanosis, edema and feeble pulse with a rate of 136. He died before anything could be done. Necropsy showed an enormous number of trichinae in the stage of encystment in the skeletal muscles. The heart muscle showed no embryos but a marked diffuse myocarditis, both a focal and diffuse type of the process. Staining showed a large number of eosinophils. Studies by Graham on rats showed that from eight to fourteen days after infested meat has been eaten, embryos can be demonstrated in the heart muscle. The fact that they are found in every situation gave rise to the belief that they reach the myocardium but are promptly disposed of. Weiss made an elaborate clinical study of the disease and called attention to the edema phenomena that occurred. Facial edema in the third week was mostly toxic from the infected muscles. In the fourth or fifth week it was largely inflammatory. In the sixth week the edema appeared in the dependent portions of the body as a result of the failing myocardium. Studies show that fatal cases are not common. There are many sublethal cases and also subclinical cases. It seems to be a curious condition if the heart disposes of the parasites. There is an analogy to syphilis. The spirochetes can be demonstrated in the aorta, but it is difficult to demonstrate them in the myocardium. It seems as if a defensive mechanism might be supposed which disposes of the parasites.

DISCUSSION

Dr. Thomas Ordway, Albany, N. Y.: The authors have spoken of these cases of trichinosis presenting myocardial symptoms. I will call attention to cases of trichinosis with the patients dying of pneumonia. I have had two such cases. There is often a very low blood sugar in cases of trichinosis. I am wondering whether the glycogen content of the heart muscle is different from that of the skeletal muscle because of its constant activity. This may have some bearing on the conditions found in the heart muscle.

Dr. George Blumer, New Haven, Conn.: I should like to ask the authors whether it is essential to assume that the parasites are destroyed. May they not, by passing through, do sufficient damage to lead to the lesions? There is an analogy to the infection in the chicken. One can infect the chicken, but the parasites do not remain in the muscle. If one examines the voluntary muscle in trichinosis the muscle shows areas of degeneration, but there are also areas of degeneration in which no trichinae are found.

Dr. Carl V. Weller, Ann Arbor, Mich.: I do not think that the myocardial weakness predisposes to the pneumonia under the circumstances. We had no opportunity to make glycogen estimations, but I think that this is a point of great interest. I do not know whether this reaction is evidence of a temporary condition or whether it represents evidence of actual destruction. I incline to the latter view because of the amount of destruction and because of the cellular reaction.

In examining the skeletal muscle we found many areas of degeneration, but, in serial sections, areas of infiltration lay above and below the areas where the parasite was present in the muscle. The very young trichinae are exceedingly small and translucent and it is exceedingly difficult to demonstrate them in the early stage in areas rich in eosinophils.

### Experimentation on the Heart in Hyperthyroidism

Dr. E. Cowles Andrus, Baltimore: Cardiac manifestations of hyperthyroidism are prominent manifestations of the disease. It is impossible, however, to correlate the severity of the heart lesion with the other clinical signs of the disease. The cardiac manifestations may be so prominent as to mask the hyperthyroidism. On the other hand, the patient may perish in the flames of a hyperthyroid crisis without showing any myocardial insufficiency.

We studied a series of 200 cases of goiter at the Johns Hopkins Hospital. We also made a study of the hearts of animals receiving thyroxine. These 200 clinical cases were taken care of first in the medical service, and later the patients were sent to the surgical wards. Exophthalmic goiter was present in 158 cases. The adenoma cases numbered 42. The latter patients were of greater age and had had symptoms for a longer time. In the exophthalmic cases the cardiac symptoms were related to the hyperthyroidism. An average time of twenty months was noted. In the adenoma class there had been goiter for several years and cardiac manifestations for years. In one case, cardiac failure was associated with symptoms for twenty-six months.

In regard to the age factor, we found that myocardial insufficiency was related to the higher decades. There were only nine patients with cardiac failure under 40 years of age. In one patient who died, Aschoff bodies were found in the myocardium. One patient, a Negress, aged 26 years, was found to have syphilis.

As regards experimental work, it is impossible to produce exophthalmic goiter in animals on account of the position of the thyroid. In experimental animals there is a latent period analogous to that seen in surgical patients before the postoperative storm. In animals under thyroxine the heart is more rapid than in normal animals. Depletion of the glycogen reserve and increase in lactic acid concentration occur. The glycogen drops from a normal of 314 to 116 mg. after the animals receive thyroxine. This is comparable to the glycogen changes in skeletal muscle. It is found that increased metabolism throws an added load on the heart, which is the cause of cardiac failure in hyperthyroidism. The heart, however, is not singled out or uniquely poisoned by thyroxine. The heart muscle merely partakes of the general metabolic upheaval set up by the hyperthyroidism and suffers depletion of the glycogen reserve. Thus, first the excessive load and secondly the metabolic changes in the muscle bring into prominence the cardiac manifestations of hyperthyroidism. This may lead, especially in older persons, to cardiac insufficiency, because the load thrown on the myocardium exceeds the limits set up by its own metabolism.

#### DISCUSSION

Dr. E. B. Krumbhaar, Philadelphia: The clinical and electrocardiographic approach to this study is of interest. Some years ago I studied a number of cases of toxic goiter before and after surgical treatment. Many cases showed ventricular preponderance. Signs were about equally divided among the patients of right and of left ventricular preponderance. After surgical treatment, examination showed that examples of increased activity in the right ventricle had disappeared; but signs of preponderance in the left ventricle showed very little change postoperatively. This seems to show that signs of right ventricular preponderance may be due to overload or there may be some other factor present, possibly not connected with the hyperthyroid condition, which causes greater and more prolonged change in the left ventricle.

Dr. J. H. Means, Boston: Dr. Andrus has gone a long way toward settling the long drawn out controversy as to whether the heart is successfully compensated. The weight of clinical evidence is that the heart tolerates this burden of work with success in thyrotoxicosis. We had one patient with thyrotoxicosis under observation seventeen years and by all examinations there was no evidence of pathologic cardiac changes at all. I think the heart is not specifically poisoned but carries on very well. If a patient has some cardiac burden and then gets a thyroid condition there is, of course, a double burden, and decompensation is apt to occur.

Dr. W. S. Thayer, Baltimore: The extraordinary capacity for cardiac recovery evidenced by some patients without anything besides thyrotoxicosis is remarkable. A woman who in 1909 had an extreme degree of right-sided insufficiency, auricular fibrillation, distended veins and general dropsy then had a subtotal thyroid removal. Her general condition was entirely reestablished, except for the auricular fibrillation. After a time she developed a slight hypothyroidism. She was given small doses of thyroid. That woman is alive and well at the present time with a slow, normal, but irregular pulse. Nothing in the history was found except the thyrotoxicosis. She was able to live a normal life after the operation. I have seen other cases not so marked, but this instance makes one feel that there should not be, at least in some instances, any great disturbance of the heart muscle.

Dr. W. J. Kerr, San Francisco: In California my associates and I have been interested in cases of hyperthyroidism with cardiovascular manifestations. We have observed auricular fibrillation in one third of the toxic cases. We have seen frequent changes in the liver going on to focal or diffuse necrosis. The heart muscle has shown marked changes in only a few cases. In other structures, such as the skeletal muscles, we have not been able to demonstrate these changes. This study was limited to the ribbon muscles of the neck. Dr. Naffziger, in our hospital, has found degeneration and hypertrophy of the extra-ocular muscles in patients with marked exophthalmos. Dr. Andrus, two years ago, reported reduced glycogen and increased lactic acid content of the muscles in experimental hyperthyroidism. Dr. Anderson, in my department, has studied the lactic acid content in the blood. In the thyrotoxic patient the lactic acid is normal during rest but is greatly increased during exercise. In the normal individual, either it does not go up or it returns very quickly to the normal level. A more careful study of those structures in which the glycogen content is normally high may reveal structural changes in the most severe or more prolonged cases of thyrotoxicosis.

Dr. E. Cowles Andrus, Baltimore: I should like to emphasize one point which Dr. Means raised, and that is that any result as regards the heart muscle must be determined by the soil on which hyperthyroidism is implanted. One cannot expect the same response from all individuals. One has to consider the age of the patient and the development of the disease. A description of the myocardial changes must be approached with caution. Dr. McEachern examined a group of patients with hyperthyroidism at Johns Hopkins Hospital and also a control group of patients dying of other conditions. There were similar changes in the hearts of the control group, and to a similar degree.

### Studies on the Circulation in Hypertensive Cardiovascular Disease by the Use of the Injection Method

Drs. W. de B. MacNider, Chapel Hill, N. C., and John Walker Moore, Louisville, Ky.: Cardiocirculatory dynamics have been hitherto considered of a mysterious nature and have given rise to conflicting theories. Our studies have been made with the idea of throwing some light on this lack of unanimity among workers. In the first place we have made a study of the normal man, as a basis from which to compare the results in hypertension. The studies were confined to a group of cases admitted to the City Hospital. The cardiac cases studied were divided into four groups: severely decompensated, moderately decompensated, compensated, and undecompensated hypertensive cases. The patient was placed in a recumbent position on the edge of the bed, and injections of scarlet red were given into the circulation.

### The Rôle of Arterial Thrombosis in Visceral Disease of Middle Life

Dr. Lewis A. Conner, New York: Whereas thrombosis in the arteries of the heart and of the brain is known to be common and is easy of clinical recognition, almost nothing is known concerning the symptoms of arterial thrombosis in the abdominal viscera. Nevertheless the frequent occurrence of degenerative changes in the arteries of the pancreas, kidneys, spleen and mesentery indicate that thrombosis in these vessels cannot be rare. The failure to recognize attacks of arterial thrombosis in the abdominal organs must be due in part to the inherent difficulties of diagnosis but is almost certainly due partly to one's failure to have the possibility of such attacks in mind. One may attempt to construct a framework of diagnosis for arterial thrombosis in the kidney, pancreas, spleen and mesentery by utilizing certain symptoms associated with thrombotic infarction in the heart (fever, leukocytosis) and those which result from infarction due to embolism in the kidney, spleen and mesentery. It seems probable that, when both internists and pathologists begin seriously to seek for evidences of such thromboses and to correlate their observations, the difficulties of diagnosis will be found to be not insurmountable and the features of the respective clinical pictures will gradually emerge from the present obscurity much as have those of the diagnosis of coronary thrombosis.

### DISCUSSION

Dr. R. C. Levy, New York: I would suggest that following the appearance of this paper by Dr. Conner there will be an increase in the statistical incidence of visceral thrombosis reported. Medical diagnosis depends on such incentive. Dr. Conner has brought this question to our attention before. An example of this notice was the diagnosis of angina pectoris, which was first made in 1768 and was recognized thereafter. In the decade 1920-1930 at the Presbyterian Hospital in New York it was interesting to see the increase in the number of diagnoses of coronary artery disease, including thrombosis. In the pathologic records the incidence was noted as 12 per cent, but on the other hand in the clinical files during that time there was an increase of 400 per cent in the frequency of this diagnosis. Following the publication of papers by Herrick and others, the interest in these various conditions was aroused, and clinicians became more alert to recognize them and record the diagnosis. Dr. Dublin, the statistician of the Metropolitan Life Insurance Company, received a letter from the Bureau of Vital Statistics in Washington stating that in the decade 1920-1930 the frequency of this diagnosis had increased 100 per cent.

Dr. Emanuel Libman, New York: Among other things of interest, Dr. Conner has brought up an important consideration; namely, the question of the possible relationship of coronary thrombosis to changes in the blood. I am strongly in favor of this conception. In fact, in 1919, in the course of a paper presented to the association, I took up this subject and stated that I felt that patients suffering from coronary thrombosis had a tendency to thrombosis in general. I drew attention to the frequency of thromboses elsewhere before and after an attack of coronary thrombosis, as, for example, in the arteries of the lower extremities, in the cerebral arteries, and in veins. For some years I have called this tendency "thrombophilia," and I have considered that while the thrombosis may at times originate from infectious processes and its incidence be influenced by the condition of the vessel wall, the process is mainly of metabolic origin, having a relationship to what are called "gouty conditions." Incidentally, I am in favor of dropping the term "gout." Recently I have found that Mendel introduced the term "thrombophilie" for the same condition and that von Recklinghausen stated that there occurs an individual tendency to thrombosis and that it had a "relationship to such metabolic disturbances as diabetes and gout." The problem of coronary thrombosis is in the main a metabolic one. It is urgent that the chemical disturbances be studied and that a great concerted effort be made to prevent coronary thrombosis. While much study is being made of this disorder, I believe the most important lines of investigation are not being at all stressed. At the risk of being considered facetious I am tempted to write a paper entitled "The Present-Day Neglect of the Study of Thrombosis of the Coronary Arteries." Dr. Levy has taken up the question of the incidence of coronary artery thrombosis formerly and now. I have the impression that the frequency is greater at the present time—and I have been studying the condition for over thirty years. In this connection the study of the incidence of cerebral thrombosis may be of great significance. Is cerebral thrombosis less frequent than it was twenty or thirty years ago? Another important question is, Does coronary thrombosis occur at an earlier age, and, if so, are those who formerly died at an advanced age of cerebral thrombosis dying of coronary thrombosis at an earlier period of life? If this should prove to be the case it would be another example of what James Paget designated "errors in the chronometry of life."

Dr. J. H. Means, Boston: Thrombosis of the pulmonary artery is a very rare condition but it exists. I had a case of complete thrombotic occlusion of the right pulmonary artery, but on account of the fact that there was an unusually rich collateral circulation through the bronchial artery the patient was able to carry on. Cyanosis and unexplained signs put us on the track of something in the pulmonary circuit. There has been a case reported in which the roentgenogram showed an oblong shadow projecting into the pulmonary artery.

Dr. A. R. Dochez, New York: During infection of the respiratory tract in individuals with arteriosclerosis there is a tendency for thrombosis to occur. Whether this is due to diffusion in the circulatory tract is not clear. But, as one goes over records, there is correlation with minor infection. This is not frequently mentioned, but it should be noted as often as it exists.

Dr. Alfred E. Cohn, New York: Last year Ehrich and I published the report of an investigation on the coronary arteries. We examined the coronary arterial system by decades in persons living a normal life. Our method of study was to analyze changes that took place in the intima of the coronary arteries. We found that the branches of the right and the left coronary artery were different in the results as regards time of life. The ramus descendens anterior was often well advanced in arteriosclerosis in the fifth decade. The ramus descendens posterior was not affected till the seventh decade. There are systemic changes that take place in these lesions which must be considered in the whole picture.

Dr. W. S. Thayer, Baltimore: Thrombophilia is a condition that is commonly associated with thrombosis of the veins or the arteries. It may or may not be related to infection. There are some cases of spontaneous venous thrombosis, and sometimes of arterial thrombosis. I saw a marked example in a woman who had multiple thrombosis, both arterial and venous, all over the body. Dr. Cohn, who was studying the coagulation of the blood, found a lower antithrombin content than he had ever seen. I think this is a condition which will have to be recognized.

Dr. Lewis A. Conner, New York: As far as Dr. Libman's views are stated, I am in entire sympathy with him. I think that there are probably subtle changes in the blood mixture which determine changes in the arteries. I do not think that evidence of this has yet been found but rather evidence as to the relation of arteriosclerosis and thrombosis. While there are cases occurring early in life, in the long run the relation between thrombosis and arteriosclerosis is striking. What is needed is accurate detailed study of individual cases. If one goes over the literature, the facts given are scanty and so many details are lacking that there is little help. Another difficulty is failure of cooperation in postmortem studies. Most of these abdominal cases go on to recovery. These cases must be studied in great detail, with years of confirmation by necropsy study. It is not an easy study but may prove to be quite possible if the necessary steps are taken.

## Some Studies on the Mechanism of Diuresis in Patients with Congestive Heart Failure

Drs. George Herrmann, C. T. Stone and E. H. Schwab, Galveston, Texas: We should like to stress the importance of edema as a clinical therapeutic problem. The methods and mechanisms of its elimination seem to warrant further studies. The spontaneous diureses of rest in bed with limited low protein, salt and water intake were noted to occur as a rule, if at all, within the first three days. Digitalization seemed to act in much the same way apparently as a result of increased general circulatory efficiency and with that improved renal glomerular circulation. The mode and point of action of the so-called specific diuretics, the xanthines and the mercurials in the accomplishment of profuse diuresis in edematous patients with congestive heart failure are still unsolved questions.

We have attacked the problem of the dissipation of cardiac edema by attempting to calculate the amount of glomerular filtration and the amount of tubular reabsorption per minute before, during and after an acute profuse diuresis. We followed the method of Rehberg, in which 5 Gm. of creatinine is ingested and the blood levels and urinary percentages are followed periodically and the ratio taken as the index of concentration. This is true if creatinine is a totally nonthreshold substance filtered entirely through the glomerular tufts and not at all absorbed by the tubular epithelium as it is assumed to be. This index of concentration multiplied by the minute volume of urine (U) gives the figure which is taken to represent the amount of filtrate per minute (F). This filtration (F) minus the urine volume per minute (U) is taken to represent *the amount of fluid reabsorbed (R) in the tubules.* The simultaneous blood and microquantitative urine analyses for chlorides and urea yield data on which the amounts of these substances filtered, reabsorbed and excreted in the urine can be calculated before, during and after the diuresis.

We have made twelve such studies in patients with edema from heart failure. In four, digitalis bodies were used by mouth, intramuscularly and intravenously to produce diuresis; in four, theophylline ethylenediamine, 0.96 Gm. intravenously, and in four mersalyl, 0.2 Gm. intravenously. The diuresis of rest, digitalization and theophylline is accomplished by an increased filtration along with some decrease in reabsorption. Such results can be explained on the basis of increased glomerular circulation and the consequent more rapid passage of the blood from the tuft through the tubular plexus, thereby decreasing minute plasma volume reabsorption. In mersalyl diuresis, on the other hand, there is no increase in filtration but definitely a sharp decrease in reabsorption to account for the increased urinary output. This is apparently due to a change produced in the cells of the tubular epithelium by the passage of mercury through them. Interesting combination effects were obtained suggesting the persistence of effects. The effects of diuretics seemed to be primarily on the kidney rather than in the tissues.

The blood and urine chemical analyses suggested that the chlorides first lost through the kidney were mobilized rapidly and in great quantity from the tissues along with other electrolytes, urea and water, and were filtered through the glomeruli, diffusing back or being reabsorbed only incompletely, and therefore being carried out along with the desired increased fluid output.

### Experimental Observations on Diuretics

Drs. Henry A. Christian and Edward A. Bartram, Boston: Various diuretics have been injected into the left renal artery of dogs under anesthesia produced by the intraperitoneal injection of diallylbarbituric acid. The urine has been collected and measured separately from each ureter.

With merbaphen, mersalyl and theophylline sodio-acetate, a small dose in the left renal artery causes a diuresis from the left kidney and no effect on the flow of urine from the right kidney. A somewhat larger dose causes an increase in flow from the left kidney, and a diuresis from the right less than that occurring from the left. As the dose is increased further, the flow from the left kidney begins to decrease while that from the right continues to increase. With still larger doses, diuresis from the left kidney ceases while that from the right kidney continues to increase. These results, which were found with an occasional exception, indicate that these mercurial and theophylline diuretics have a direct action on the kidney.

With theobromine sodiosalicylate and caffeine citrate, usually there is approximately the same flow of urine from each kidney when the diuretic is injected into the left renal artery, the diuresis increasing to an equal degree from each kidney as the dose of the diuretic is increased. These results harmonize with but do not prove that the theobromine and caffeine diuretics have an extrarenal effect.

The conclusion seems justified that diuretics, as represented by those used by us, may be divided into two groups with different pharmacologic action.

### The Effects of Diuretics on Water and Salt Metabolism

Dr. Herrmann L. Blumgart, Boston: In studies dealing with the clinical effects and mechanism of diuretics, an attempt was made to influence the examination of the urine in the effort to render it as constant as possible. The patients were placed under strict metabolic control. The time and amount of the dosage were uniform. Urine was collected seven times daily. The specimen was analyzed for sodium, potassium, calcium, ammonia, phosphates, sulphates and acidity. The stools were analyzed. A definite daily curve of excretion was found the best method for obtaining effects of the diuretics. The studies were begun on a group of normal subjects in whom the diuretics caused increased excretion of the urine as to both volume and constituents. No changes occurred in the ammonia, acidity or inorganic phosphates and sulphates. In the normal subject it was found that 90 per cent of the body fluids excreted were extracellular and 10 per cent intracellular. The mercury diuretics had more marked effects than the xanthine diuretics. If the dose was doubled, the effect was trebled. Tubular reabsorption ran parallel to the increased diuresis. Diuresis may take place without the glomerular filtration being affected. Another group of subjects studied were patients with cardiac decompensation. The drugs used were theobromine sodiosalicylate, mersalyl, merbaphen and theophylline. In this group of patients, instead of 10 per cent intracellular body fluid being affected, the proportion was 30 to 40 per cent.

#### DISCUSSION ON DIURETICS

Dr. J. C. Aub, Boston: I should like to ask Dr. Herrmann what he terms defective reabsorption.

Dr. Norman M. Keith, Rochester, Minn.: The remarks of Drs. Herrmann, Stone and Schwab as to the comparative diuretic action of digitalis, caffeine derivatives and mercury are of clinical significance. In their experience, and in that of many others, digitalis is less effective than mercury and caffeine, and this fact needs to be emphasized. The results of Drs. Christian and Bartram with mercury show the importance of dosage and the undoubted toxicity of large doses to the kidneys. Dr. Blumgart has compared the reaction of diuretics in the normal subject and patients with edema under controlled conditions. Such a method has been distinctly productive for several years. As Dr. Blumgart has pointed out, the diuretic action in the normal subject and in cases of edema may be different. His suggestion is that this difference may be due to the chief effect being exerted in either the intracellular or the extracellular fluid. This question must be studied further to determine whether such differences are peculiar to distinct types of edema states.

Dr. W. deB. MacNider, Chapel Hill, N. C.: Drs. Christian and Bartram said that they studied the effects of different types of diuretics in different types of renal lesions. Did they carry this work out in animal experimentation as well as clinically?

Dr. George Herrmann, Galveston, Texas: We used filtration to determine the creatinine ratio in the urine and in the serum. Reabsorption was shown by the difference between the concentration in the urine and the blood creatinine. For each of the substances used, we estimated the level of the chloride and urea in the blood in percentages. We subtracted the filtered amount in the excreted urine and this gave us the reabsorbed amount.

Dr. Henry A. Christian, Boston: In answer to Dr. MacNider, I have not done experiments on any but normal animals. The effect of mercurial diuretics is most injurious to the kidneys of animals, as judged by the albuminuria which is always produced in dogs to a marked degree. It is curious that this should be so when there is most diuresis, but it is due to increase in reabsorption.

Dr. H. L. Blumgart, Boston: Edema varies in different types of the disease. In the cases studied the percentage of intracellular fluid was normal, but in some cardiac patients the percentage of the intracellular fluid was much greater as compared with the extracellular fluid. Intracellular edema is not always present. It depends on the stage of the pathologic changes present in the cardiac disease.

# Current Medical Literature

## AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Issues of periodicals are kept on file for a period of five years only. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending, but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Pyuria and Pyelitis: Influence of Exsiccosis on Their Experimental Production. C. C. Stewart, Rochester, Minn.—p. 632.

**Vitamin B Complex.**—Ross and Robertson placed a group of young rats on a vitamin B-free diet, and a second group on a similar diet plus 6 per cent dried brewers' yeast. Both groups were infected by mouth with an enteritidis organism. Of fifty-three rats on the diet deficient in vitamin B ten, or 19 per cent, survived the infection, whereas of fifty-one rats given the yeast in addition, thirty-eight, or 75 per cent, survived the infection. The authors conclude that the addition of the vitamin B complex to the diet lacking in this factor increased the resistance of the rats against infection.

**Coagulation of Blood of the New-Born.**—Sanford and his associates exposed ten new-born infants to ultraviolet radiation by means of an air-cooled mercury vapor quartz lamp of 110 volts, 60 cycles and 10 amperes. A voltage of 70 was always administered and maintained throughout the exposure. The dorsal and ventral surfaces were exposed for two minutes each daily, and the time was increased one minute a day until the length of the exposure was eight minutes. Next, ten new-born infants were given 3 drops of viosterol in oil 250 D on the second day, and the dose was doubled each day until 96 drops was given; this dosage was used for two days. Examination of the blood revealed that either exposure to ultraviolet radiations or the administration of viosterol 250 D, or both tended to increase the fibrinogen of the coagulation substance to a slight extent, and to decrease the antithrombin, thereby increasing the tendency of the blood to clot.

**Serum Therapy in Meningococcus Meningitis.**—Lyon reports four cases of meningococcus meningitis in which he gave large doses of serum by introducing the serum into the ventricle and simultaneously withdrawing fluid from the spinal subarachnoid space. The cerebrospinal fluid became sterile within from thirty-six to forty-eight hours. These patients, given but two injections of serum, received large doses of serum at each injection; in this respect the desideratum was approached, i. e., a high concentration of serum in the cerebrospinal fluid with a chance for maximum and speedy toxin neutralization, agglutination, bacteriolysis and phagocytosis, and a wide distribution of the serum throughout the cerebrospinal fluid system. A child of 9 months took from 60 to 70 cc. of serum at one administration. A child of 3½ years took from 90 to 100 cc. The major portion of this serum remained within the cerebrospinal fluid system, even if from 10 to 20 cc. more fluid was removed than was introduced. This gives some idea of the amount of serum that may be substituted for cerebrospinal fluid by this method of serum administration or "substitution." The method was not severe on the patients so treated, and unfavorable reactions did not occur. The patients were singularly free from increased depression or other untoward effects, such as one might anticipate from such a form of treatment. Clinical improvement was remarkably speedy and satisfactory. This method is particularly valuable in the case of an infant with a patent anterior fontanel. In such cases it may be employed with ease. In infants the incidence of complications and the mortality rate is usually highest. Because of the decreased number of administrations of serum, and the shorter period of serum therapy made possible by this method, the chances of an Arthus phenomenon occurring would be greatly reduced. This method of substituting serum for cerebrospinal fluid is presented with the realization that such a small series of cases cannot be more than suggestive of possible results. It is a method that may be employed with relative safety to the patient. It makes possible a greater dosage and a wider distribution of serum than may be had with other methods. It should be effective in preventing, as well as removing, complicating obstructions. The method should produce a higher percentage of complete recoveries, and quicker recovery than any method of serum therapy now in use.

**Atelectasis in the New-Born.**—According to Dunham, atelectasis of the lungs in new-born infants is the abnormal persistence of the fetal state of the lungs due to some condition that interferes with the normal functioning of the respiratory center or to mechanical obstruction of the air passages. The chief symptom of atelectasis is cyanosis. Cyanosis due to atelectasis of the lungs can be differentiated from cyanosis caused by other conditions by means of roentgenograms. The roentgenographic picture of atelectasis of the lungs in the new-born is characterized by haziness of the lung fields, which is evidence of lack of complete aeration, and by the abnormal shape of the thorax and the abnormal position of the ribs, which are evidence of incomplete expansion of the lungs. The author emphasizes the fact that roentgenographic examination of the lungs is always indicated when a new-born infant is cyanotic.

**Esophageal Obstruction.**—Stokes and Wilder studied the effect of complete closure of the esophagus with the loss of saliva on the life and growth of a child of 10 years. Such closure appears to have no serious effect provided a well balanced diet is supplied. The addition of saliva and other secretions of the mouth to the food is probably unnecessary for the maintenance of a state of nutrition at least approaching normal. Experimentally, the authors produced esophageal fistulas by means of a three stage operation on young pigs. This work furnished evidence that growth will proceed at a rapid rate in this particular animal despite a complete loss of saliva.

**Migratory Peritonitis.**—Wile and Saphir report that twenty-four cases of peritonitis, twenty-one of which were diagnosed clinically as hematogenous peritonitis, proved at necropsy to be the result of an invasion of the peritoneal cavity by bacteria from primarily diseased intraperitoneal organs or structures close to the peritoneum, without perforation or without direct extension of the inflammatory process to the peritoneum. Sixteen of the twenty-four cases showed enteritis. The term "migratory peritonitis" seems appropriate for this type of case, because it corresponds with the German term "Durchwanderungs-Peritonitis" and signifies the pathogenesis of this form of peritonitis. The authors believe that clinical reports of cases of hematogenous peritonitis without necropsies, or with necropsies but without complete histologic examination of the gastro-intestinal tract, such as comprise the bulk of the literature of so-called hematogenous peritonitis, should be discarded. Many of the cases in which the condition was reported as hematogenous peritonitis are examples of migratory peritonitis. The evidence supporting the occurrence of peritonitis directly following a blood stream infection without an intermediary lesion within or adjacent to the peritoneal cavity is inadequate. So-called hematogenous peritonitis may occur as part of a generalized metastatic pyemic process that results in abscess formation or infected thrombi within or adjacent to the peritoneal cavity. The ensuing peritonitis is the direct result of the abscess or thrombus. It is unlikely, however, that this form of peritonitis does occur in the absence of other metastatic pyemic phenomena.

**Pyuria and Pyelitis.**—Stewart produced pyelitis in fourteen of forty-five rabbits by infusions of 20 per cent solution of sucrose. In thirteen of twenty-eight animals that had received four or more injections, pyelitis developed. Repeated injections and longer survival of the animals increased the incidence of urinary infections. The situation of the inflammation in the lining of the pelvis and the absence of cortical abscesses are strong evidence that the lesions were due to ascending infection. There is no evidence to show whether this occurred by way of the lumen of the ureter or the accompanying lymphatic channels. Some possible explanations of these observations are considered. A logical conclusion is that the injection of sucrose lowered the resistance of the kidneys to infection. That this can result from a decreased water content of the body was shown in mice by Schiff. The mechanism by which this lowered resistance is brought about is not known. The effect of decreased intake of water was studied in rats, guinea-pigs and dogs. In spite of rigorous restriction of fluids, pyuria was observed only once, in a guinea-pig without bacilluria. There was no histologic evidence of inflammation of the urinary tract in any of the animals. From these observations it seems improbable that withdrawal of water from the tissues alone was responsible for the pyelitis produced in rabbits. The symptoms of toxicosis as described by Kramár appeared only in the two dogs, but in these animals pyuria did not develop. Definite conclusions cannot be drawn from so few experiments. It has been established, however, that a similar picture does not result in rats or guinea-pigs. Pyuria occurred only once in these animals, and thus it seems improbable that it was related to the exsiccosis.

Analogies and Differences of Second and Eighth Nerves and End-Organs: Generalizing Preliminary Considerations: II. Anatomic. C. B. Walker, Los Angeles.—p. 329.

**Granular Conjunctivitis in Monkeys.**—Four of five monkeys in which folliculosis was produced by Thygeson yielded Bacterium granulosis. The disease differs from human trachoma mainly in the absence of pannus. The author concludes that etiologic relationship of this organism to human trachoma can never be established by monkey experimentation.

**Tonometry Before and After Cataract Operation.**—Ferrer advises the routine use of the tonometer in the examination of eyes preliminary to cataract extraction. In the majority the tension will be found normal and choice of operative procedure is unrestricted. In those with subnormal tension it is advisable to dilate the pupil widely with atropine to promote ease of delivery of the lens, which is liable to be luxated by pressure. In eyes showing notably increased tonus, atropine is a source of danger. The tension should be lowered by suitable measures before extraction of the lens. Tonometric measurement may be made by the twelfth postoperative day if anything abnormal is noticed. The use of atropine is objectionable before or after discission. It is never necessary and frequently dangerous, as hypertension is apt to follow this operation as the result of imbibition of aqueous into the vitreous.

Electrosurgery in Rhinolaryngology: A Solution for Tonsil, Turbinate and Sinus Problems. L. J. Silvers, New York.—p. 154.
Ultraviolet and Infra-Red Glasses. S. English.—p. 164.

**Roentgen Therapy in Anterior Poliomyelitis.**—Le Wald calls attention to the fact that opinions regarding the specific value of roentgen therapy in anterior poliomyelitis are divided even among foreign workers. It should be noted, however, that nowhere among those using the method has there been voiced any distinct opinion against its use or its harmfulness. On the basis of what has already been accomplished, radiation therapy promises definite amelioration and improvement of certain symptoms and hence may well be considered as a potent therapeutic adjuvant in the management of anterior poliomyelitis.

**Scope of Electrosurgery in General Surgery.**—According to Ground, electricity has a wide field of usefulness in gynecology, and few there are who can practice this specialty successfully without its use in some form. Electrocoagulation is being utilized by many gynecologists, but there is no reason why the general practitioner who is, so to speak, electrically and gynecologically inclined, cannot use this very beneficient agency with equal readiness.

Tumors in Posterior Cranial Fossa with Mental Symptoms: Three Cases. R. W. Southerland, New York.—p. 144.

**Motor Activities in New-Born Infants.**—Investigation of the reflex reactions in infants during the first ten days of life lead Chaney and McGraw to the following conclusions: Individual differences are evident in the simplest type of reflex reaction in new-born infants; the more complex the type of reaction, the more marked is the individual variation. Although there is great variability in type of reaction among new-born infants, the total absence of any active reflex response is strongly suggestive of a pathologic condition. For example, an infant's response to plantar stimulation may be dorsiflexion of the toes, plantar flexion of the toes, or some other reaction pattern, but the absence of any reaction whatever is so unusual that it calls for a search for evidence indicating some abnormality or something pathologic. There is nothing in the investigation to substantiate the contention that certain reflex patterns, such as the Babinski (considered of pathologic significance when present in adults), is in infants a normal reflex reaction attributed to an immature nervous system. Reflex reactions of normal new-born infants are different from the characteristic reflexes of normal adults; but they are different also from the classic pathologic reflex patterns.

**Familial Periodic Paralysis.**—Zabriskie and Frantz report the case of a man, aged 23, with a rather severe form of familial periodic paralysis. His mother suffered from the same disease and in all probability died from it. Examination during an attack showed a decrease or abolition of the deep reflexes, a slowing of muscular decontraction after reflex or electrical stimulation, a diminution or loss of the electrical excitability of the muscles, and at times an enlargement of the heart to the left with an apical systolic murmur. All these observations have been noted repeatedly by other clinicians. The chemical constituents of the blood were within normal limits during the free intervals and during the attacks; in particular, alterations in the calcium content were not found. A somewhat increased tolerance for dextrose was noted. Microscopic examination of specimens of muscle removed at biopsy showed a vacuolization of some fibers and in places a granular substance in these vacuoles. Partial attacks were repeatedly induced by local cooling, in confirmation of the work of Neel. During the induction of such attacks and during the artificially accelerated recovery (by local heat) the steady decrease of electrical excitability could be followed to its extinction, and then the rise of this excitability was again watched. What the authors believe to be a new contribution is the demonstration of an extraordinary fluctuation in the creatinine output with the patient under standard conditions. This is probably the expression of a fundamental disorder of muscular metabolism. The variable, but generally high, fluid intake and output is also in keeping with previously published observations. The striking differences noted in oxygen consumption between excised portions of paralyzed and nonparalyzed muscles is also a new observation. It must be emphasized, however, that this is an isolated observation and proper weight can be given to it only after further similar experimental studies have been made. Finally, chemical analysis of the muscles showed a low total inorganic phosphate, low creatinine and very low organic acid soluble phosphorus.

**Improved Method of Encephalography.**—Davidoff and Dyke emphasize that it is possible to obtain good encephalograms with much less air than is usually introduced, and thereby to decrease materially the discomfort of the patient both during and after the procedure. The severity and duration of the symptoms occurring during and after lumbar air injection seem to depend on the amount of air used, not, however, in absolute terms, but relative to the size of the ventricles. The authors have learned to determine the amount of air necessary in any given case by taking a film after 20 cc. of air has been introduced, and immediately developing it. Inspection of this film shows whether the ventricular system is normal in size or whether it is dilated. If the size of the ventricles is within normal limits, from 50 to 70 cc. of air is sufficient for excellent encephalograms. Furthermore, they are convinced that stereoscopic roentgenograms from four sides with the head both vertical and horizontal are necessary for the proper interpretation of the encephalograms. They have followed this procedure for two years in more than 300 cases and have been able to demonstrate that the practice of taking the films in only the vertical or horizontal position may lead to erroneous interpretations. This relatively large number of exposures entails no danger to the patient.

**Meningeal Fibroblastomas.**—Elsberg believes that for the approach to a tumor underneath the temporal lobe, whether the growth is derived from the dura of the floor of the middle cranial fossa or from that of the sphenoid ridge, the base of the bone flap must be as low in the temporal region as possible, and bone should be rongeured away below the bone flap until the base of the skull has been reached. If the neoplasm is attached to the sphenoid ridge and is to be approached by elevation of the frontal lobe, the flap that is outlined should extend forward almost to the frontal sinus; while if the tumor lies farther back, the scalp incision may be made entirely within the hairline. After the bone flap has been turned down and the bone has been rongeured away down to the base of the skull, an incision should be made in the dura low in the temporal region. If the neoplasm is exposed or its position located, the dura incision should be enlarged forward and backward, and a dural flap formed with its base upward. This dural flap should be large, so that there will be room for the elevation of the temporal lobe without undue pressure on this and adjacent parts of the brain. In order to expose the growth fully, a small secondary flap must often be made by incisions in the dura downward toward the base of the skull. When the layer of cortex that lies over the growth is thin, it is usually advisable to excise it or to make an incision through the brain tissue down to the surface of the neoplasm. On the other hand, if a considerable part of the temporal lobe covers the growth, the attempt must be made to elevate the lobe by slowly wiping it away at the same time that the brain is raised with a retractor. As soon as one is certain that the neoplasm is attached to the dura on the floor of the middle fossa and especially if intracranial pressure is not much increased, the attempt should be made to separate the dura from the bone underneath the temporal lobe, in a similar way to that done in operations for trigeminal neuralgia. By this procedure it may be possible to expose and plug the foramen spinosum with waxed cotton, and by this means to occlude the middle meningeal artery. This vessel or its branches supply a great deal of blood to growths in this situation, and the advantage gained by occluding it is evident. If, however, the bleeding is excessive while the dura is being separated from the bone, or if the pressure is so great that the dura cannot be elevated without undue force, the procedure cannot be carried out. It is seldom, if ever, advisable to attempt to deliver the tumor in toto unless the growth is soft in consistency and every part of the tumor bed can first be brought into view by drawing the growth in one or another direction. In the large hard growths it is always better to remove the central part with the electric knife before attempting to separate the brain from the tumor capsule. The gradual raising of a firm growth out of its bed can sometimes be successfully accomplished, but there is always the danger that vessels in the deeper part of the tumor bed will be torn and a troublesome if not serious bleeding will occur. The larger the author's experience with these growths has become, the more often has he attempted to excise the attached part of the dura by separating it from the bone. No operation for a meningeal growth is ever ideally complete unless the dural attachment is removed together with the growth. Cauterization of the inner surface of the membrane with the electric current or with Zenker's solution is often the best that can be done; it is frequently an efficacious though not an ideal procedure. When there is a marked hyperostosis on the floor of the middle fossa, it is seldom possible to do a radical operation and a late recurrence of symptoms may be expected.

**Serologic Reactions with Hemolytic Streptococci in Acute Bacterial Infections.**—Tillett and Abernethy present observations which demonstrate that serums from patients acutely ill with a variety of bacterial infections are capable of agglutinating certain strains of hemolytic streptococci. During the course of an acute illness, the capacity of a patient's serum to react is demonstrable early after onset, persists during the active stage, and disappears soon after recovery. Four strains of Streptococcus hemolyticus, derived from different diseases, are agglutinable. Agglutinability is destroyed by heating cultures to the thermal death point. Agglutinable cultures killed with solution of formaldehyde are not altered. The protein fraction of serum precipitated by carbon dioxide under conditions described contains the constituent reactive with streptococci. By this method, serums from cases of typhoid were fractionated and the agglutinins for typhoid bacilli and hemolytic streptococci were separated.

**Staphylococcus Aureus.**—According to Pinner and Voldrich, apathogenic Staphylococcus albus, Staphylococcus citreus ad Staphylococcus roseus are split off spontaneously from pure line strains of Staphylococcus aureus. The splitting off of Staphylococcus albus can be much enhanced by growing Staphylococcus aureus in broth containing aureus agglutinins and by animal passage. The three nonidentical strains derived from Staphylococcus aureus appear to be stable under ordinary conditions. They differ from the mother strains in regard to pigment production, growth intensity, individual morphology, staining reactions, virulence, fermentative and proteolytic action, hemolysin production, alkali production, agglutinability, immunizing properties and susceptibility to bacteriophage. From albus strains aureus strains can be recovered by cultivating the albus strains for prolonged periods in mediums containing high concentrations of antialbus serum. The relation between aureus and albus strains is essentially similar to that between S and R strains of other micro-organisms.

**Bacteriology of Bronchiectasis.**—Greey did not find a uniform bacterial flora in nine cases of bronchiectasis. Bacteria of various types were obtained in each of the cases studied. The absence of spirochetes in five of the cases suggests that their presence in the other four was a chance invasion. This also holds true for the other micro-organisms isolated. Pure cultures of a single type of streptococcus were obtained from the bronchi following lobectomy on three occasions, which indicates that a mixed infection is not necessarily present. The variety of micro-organisms recovered suggests that no specific type is an etiologic factor but that many bacteria are capable of producing bronchial damage sufficient to favor dilatation.

**Nature and Properties of Virus of Herpes.**—Holden states that the enhanced resistance of desiccated herpes virus to deterioration, heat and the action of certain chemicals is striking when compared with the resistance of moist herpes virus to the same factors. A comparison of the resistance of pneumococci, both moist and dried, to chemical agents and heat, with the resistance of herpes virus under similar conditions, furnishes results that are not inconsistent with the assumption of the living nature of the virus.

**Absorption of Precipitins.**—Hektoen and Delves describe experiments in which they demonstrated that precipitins in multivalent serum may be removed successively with reasonable success by the selective action of single antigens. The successive absorptions were carried out by treating the same sample of antiserum with several antigens, one after another. After each treatment or absorption, the precipitate was removed by centrifugation and the serum tested with the antigens involved in the experiment.

**Action of Bacteriophage Against Colon Bacillus.**—Applebaum and MacNeal report that purulent exudate, even when diluted, exerts an interfering influence on the lytic action of bacteriophage against the colon bacillus, provided the colon bacillus is capable of active growth in the medium employed. Human blood serum and rabbit blood serum exert a similar but less powerful interfering influence, which becomes evident when pathogenic strains of the colon bacillus recently obtained from human infections are employed. Whole blood produces an effect similar to that of serum. Suspensions of erythrocytes in an indifferent medium seem to exert little, if any, influence on the bacteriophage phenomenon in relation to the colon bacillus. These observations have a bearing on the use of bacteriophage in the treatment of infectious disease.

Notes on Alexander Ramsay and His Anatomic Manuscripts. J. F. Ballard, Boston.—p. 681.
Progress in Pediatrics. J. L. Morse, Boston.—p. 683.

**Significance of Precordial Tenderness.**—Kellogg and White call attention to the fact that precordial tenderness may occur in an individual with a hypersensitive nervous system, whether or not there is serious heart disease. In a series of 328 cases of definite precordial tenderness that they observed, the condition was more often found when there was a combination of heart disease and nervousness than with either condition alone. The factor of nervous irritability and fatigue is certainly of greater importance in the production of the sign than is organic cardiovascular disease itself, for in cases of very severe acute and fatal coronary thrombosis there may be no tenderness whatever, and in many nervous individuals with perfectly normal hearts there is well marked precordial tenderness.

**Aseptic Anastomosis of Intestine.**—Briggs and Whitaker describe a new method for aseptic anastomosis of the intestine by electrosurgery. It consists essentially in devitalization by fulguration of an area the size of the proposed stoma on either end or side of the intestine to be joined, followed by careful approximation and fixation with a double row of mattress sutures. The advantages are ease of execution, reduction of trauma and danger of contamination to a minimum, and accurate coaptation of the joined edges without excessive infolding. The only disadvantage is blockage of the intestine for from twelve to twenty-four hours until the devitalized "button" sloughs out. Since, however, in obstructive cases enterostomy or colostomy should always be performed, there is no real objection on this ground. Experimental results have been excellent.

Rat Infestation Inspection of Vessels. C. L. Williams.—p. 765.

**Relation of Oxidation to Proteolysis in Malignant Tumors.**—Voegtlin and Maver believe that for the proper understanding of the proteolytic mechanism of the tissues in living animals it is essential to perform experiments in vitro under conditions approximating those in vivo. They made an attempt in this direction in the case of malignant tissues by reducing the oxygen tension and adjusting the hydrogen ion concentration accordingly. The in vitro autolysis of two malignant tumors showed that both $p_H$ and oxygen tension are controlling factors in tissue proteolysis. These factors apparently operate through their influence on the sulphydryl system of the tissues. The authors present evidence which indicates that not only glutathione but also proteins containing SH groups are concerned in tissue proteolysis. Confirmatory evidence is obtained from experiments dealing with (1) the digestive action of papain on coagulated egg white containing protein SH groups, and (2) the action of papain on gelatin and fibrin in the presence of reduced glutathione. The results afford substantial proof for the coupling of oxidation-reduction and proteolysis in tissues.

**Surgical Treatment of Thyrotoxicosis.**—Richter performed radical thyroidectomy on 1,235 patients suffering from thyrotoxicosis. But few of these patients were not completely relieved of their symptoms by the operation. Reoperation was done on twenty-three, and, of these, twenty-one were relieved as shown by clinical symptoms and metabolism tests. One patient required a third operation to secure this result. Three patients made normal recoveries and had two or more normal postoperative metabolism tests, to be followed by recurrence of thyrotoxicosis. These cases can be properly designated as "relapses." One of these was shown to be due to inadequate removal of thyroid tissue. On the basis of his observations the author concludes that, in the hands of competent surgeons, radical thyroidectomy seems to be the most satisfactory treatment for thyrotoxicosis. The evidence presented showing the value of radiologic treatment is faulty because of failure to present adequate preoperative and postoperative studies of the patients treated. The immediate mortality with the radiologic treatment, while low, is misleading in view of the shortening of life expectancy with the incomplete relief from the thyrotoxicosis that may occur in many of the cases.

**Roentgen Treatment in Goiter Illness.**—Williams reports the results he obtained in 200 cases of goiter by means of roentgen irradiation. The patients averaged ten treatments over a period of three and one-half months. The average drop in pulse was 24.2 beats; average gain in weight, 8 pounds (17.6 Kg.), and lowering in metabolic rate, 23 points. One hundred and sixty-one patients, or 80.5 per cent, were definitely cured. Twenty-seven, or 13.5 per cent, were improved, making a total of 188, or 94 per cent, either cured or improved. Eight, or 4 per cent, recurred after one year, five of which were later retreated and cured. Only two patients, or 1 per cent, developed subthyroid symptoms, and only one case, or 0.5 per cent, showed telangiectases. The author emphasizes the importance of unhurried diagnosis and frequent metabolic rate check.

**Syphilis of Eighth Nerve.**—According to Garrott, syphilis of the eighth nerve occurs in two chief forms, neurolabyrinthitis syphilitica, or early auditory syphilis, and labyrinthitis syphilitica tarda, or late auditory syphilis. Neurolabyrinthitis syphilitica responds favorably to treatment in the majority of cases; labyrinthitis syphilitica tarda does not always respond as favorably in as many cases, but many of the cases are checked or stopped in their progress. The author believes that syphilis of the eighth nerve or its branches is more common than the diagnostic records of most otologists would indicate. If diminished bone conduction is just ground for suspicion of syphilis of the eighth nerve and its branches, and if it is an early manifestation of nervous system syphilis, otologists should be more alert and watch for it more carefully. Though one may not relieve all the auditory symptoms, one is obliged to recognize the systemic nature of the infection and cooperate with competent serologists in the treatment of it. By the same token, the serologist and the general practitioner should remember the possibility of eighth nerve involvement and consult the otologist. And he should attempt to outline his treatment according to the degree of involvement as determined by the otologist.

Pleuro-Enteritis. C. M. Bray, Morgantown.—p. 167.

**Cutaneous Manifestations of Syphilis.**—Matthews enumerates the characteristics of late syphilis of the skin as follows: (1) solitary, or at most few lesions; (2) asymmetry, though by no means invariable; (3) induration, deep palpable infiltration; (4) indolence; a relatively low grade inflammatory process; (5) arciform configuration, the borders being polycyclic or forming segments of circles, both in the individual lesions and in the group of lesions; (6) sharp margination, punched out appearance in ulcers; (7) tissue destruction and replacement without ulceration; (8) tendency to central or one-sided healing with peripheral extension; (9) scar formation: superficial, atrophic and noncontractile scar retaining the arciform shape of the original lesion, and (10) peripheral hyperpigmentation of rather persistent character. No one of these ten individual items can be accepted alone, but the combination often becomes an element of great value and should be carefully considered in interpreting the Wassermann reaction.

Thoracic Metastases in Ovarian Carcinoma: Report of Case with Remarks. H. T. Evans and G. I. Strachan.—p. 519.

**Cereal-Free Diet and Dental Caries.**—Mellanby and Pattison gave a group of children averaging 5½ years of age a cereal-free diet rich in vitamin D and calcium for a period of six months. The teeth of the children were defective in structure (hypoplastic), and much active dental caries was present at the beginning of the investigation. Initiation and spread of caries were almost eliminated by these diets, and the results were better than those of a previous investigation in which the vitamin D alone was increased in a diet containing bread and other cereals. Active caries was arrested on this cereal-free diet to a greater extent than in the previous investigations, when cereals were extensively used. The practicability of giving a cereal-free diet to children has, of course, to be considered. No difficulty was encountered in the elimination of cereals from the food, although the children did not like giving up bread. These children were in an institution and were confined to bed, but it would obviously be more difficult to give the diet to active children, especially if living at home. The tests do not indicate that in order to prevent dental caries children must live on a cereal-free diet, but in association with the results of the other investigations on animals and children they do indicate that the amount of cereal eaten should be reduced, particularly during infancy and in the earlier years of life, and should be replaced by an increased consumption of milk, eggs, butter, potatoes, and other vegetables. They also indicate that a sufficiency of vitamin D and calcium should be given from birth, and before birth, by supplying a suitable diet to the pregnant mother. The teeth of the children would be well formed and more resistant to dental caries instead of being hypoplastic and badly calcified.

**Malignant Disease of Hypopharynx.**—Trotter believes that the final results of operative treatment in malignant disease of the hypopharynx must be considered from two points of view: first, freedom from recurrence, and, second, the condition in which the patient survives. He emphasizes the value of precise local knowledge of the epitheliomas of the pharynx in dealing with them by operation. Such knowledge makes possible the exact orientation of any necessary operation, and so increases the prospect of cure and at the same time diminishes the need for mutilation. The view is sometimes expressed that the more extensive an excision the more likely is it to be successful; this is by no means necessarily true, for if the operation is not exactly oriented in regard to the growth its mere extent is unlikely to save it from failure. This criticism applies to many cases in which extirpation of the larynx is practiced in dealing with pharyngeal growths. There are only a few cases in which that formidable mutilation is of use in the treatment of such growths. Most of the cases in which the tumor cannot be removed without laryngectomy are incurable by any operation, and when the tumor can be removed by local excision the mere addition of laryngectomy gives no further security. In a small number of illustrative cases mentioned, the only residual disabilities left have been the occasional fixation of one vocal cord, and in one case some fibrous constriction of the esophagus. The author would not feel able to record as a true success the cure of a pharyngeal carcinoma won at the expense of laryngectomy. He considers that one of the most beneficent effects of the introduction of radiotherapy has been its tendency to make one look with increasingly critical eyes at treatment by crudely mutilating operations.

**Management of Urinary Calculi.**—Jacobs states that, except in some special circumstances, stones in the kidney should be removed. If that is not done destruction of the organ will generally result, bringing in its train chronic ill health and possibly death from renal failure. It should also be remembered that the irritation produced by a calculus of long standing may predispose to squamous carcinoma of the renal pelvis. The author has had two patients who confirm this hypothesis. In both, the kidney was removed because of extensive destruction resulting from multiple calculi, and histologic examination revealed the presence of a squamous carcinoma which had not been suspected prior to operation. One patient was a man of 54, whose history suggested that calculus formation had started eighteen years previously. The other patient was a man of 69, who dated back the onset of his symptoms to boyhood. If a minute renal calculus is not causing the patient much pain an expectant attitude may be adopted, particularly when the pyelogram shows that no damage is being caused to the kidney. The patient should take abundant bland fluids and be kept on urinary antiseptics. Periodic lavage of the renal pelvis through a ureteral catheter, followed by an instillation of silver nitrate, may help to mobilize the stone and keep the kidney free from infection.

*Disseminated Sclerosis: Clinical and Serologic Observations During Experimental Vaccine Treatment. J. Purves-Stewart and F. D. M. Hocking.—p. 605.
*Complement Fixation in Rift Valley Fever. J. C. Broom and G. M. Findlay.—p. 609.
Rift Valley Fever. R. Daubney and J. R. Hudson.—p. 611.

**Treatment of Anemia.**—Witts states that, in the treatment of acute hemolytic anemia, iron, arsenic and removal of septic foci do no good. Liver has been introduced too recently for its value to be assessed, and it has been used only in cases in which the patients might well have recovered by their own forces. The most striking feature of the treatment of acute hemolytic anemia is the dramatic effect of transfusion, often observed in patients who seemed moribund. The temperature falls and a rapid recovery sets in. More than one transfusion may be necessary to arrest the hemolytic process, but in cases properly treated by transfusion, death is a rare event.

**Multiple Sclerosis.**—Purves-Stewart and Hocking report that in 22 early cases of multiple sclerosis in which treatment by autogenous vaccine was used all the patients except 2 showed arrest or clinical improvement. In 62 moderate cases one fifth continued to deteriorate, while the remaining four fifths either ceased to progress or improved. In 17 advanced cases, 5 continued to progress while 12 remained unchanged. Of 22 early cases, all of which yielded positive cultures of spherules in the cerebrospinal fluid, 3 became culturally negative after treatment by an autogenous vaccine and 6 became less marked, while 15 remained unchanged. Of 62 moderate cases, 4 became culturally negative, 17 became less marked and 34 remained unchanged, while the remaining 7 became more strongly marked. Of 17 advanced cases, 3 became culturally negative, 3 became less marked and 10 remained unchanged, while 1 became more marked. The presence of a characteristic colloidal gold curve was confirmed. In 8 of 101 cases, this curve became negative. Definite improvement was seen in 35 cases; 11 cases became more marked, while 47 remained unchanged. The globulin reaction was positive in 72 cases at the outset; in 24 of these the reaction became negative or very faintly positive. The albumin content in all cases was within normal limits.

**Complement Fixation in Rift Valley Fever.**—According to Broom and Findlay, Rift Valley fever, the etiology of which was first determined by Daubney, Hudson and Garnham in 1931, is a virus disease of no little importance to sheep and cattle farmers in British East Africa, where it causes a high mortality in young lambs and pregnant ewes. The fact that the disease is transmissible to man and that in certain respects the clinical symptoms resemble those of dengue, sandfly fever and yellow fever, renders accurate diagnosis essential. Specific complement fixation occurs with the serums of men, monkeys, sheep, rats and mice recovered from Rift Valley fever when an antigen of the livers of rats and mice infected with Rift Valley fever is employed. Complement-fixing antibodies are well developed in the serum fourteen days after infection, and they persist for at least six months. Complement-fixing antibodies may appear in the serum in the absence of any definite illness as a result of repeated exposures to infection. The degree of complement fixation is in the case of men, sheep and monkeys roughly proportional to the severity of the clinical symptoms. Mice and rats produce only small quantities of both complement-fixing antibodies and protective antibodies. Dried liver as an antigen gives less satisfactory results than fresh livers of infected animals.

**Tuberculosis in Childhood.**—Webster presents the results of an investigation of eighty-one children with varied manifestations of tuberculosis, and five adults with bone and joint tuberculosis. Bone and joint tuberculosis, bronchial lymph node and lung tuberculosis, and tuberculosis of the brain and meninges were found to be due invariably to the human type of Bacillus tuberculosis. Tuberculosis of the cervical lymph nodes and tonsils was shown to be of bovine origin to a predominating extent, the number of bovine infections in a series of twenty-four cervical lymph nodes being seventeen (70.8 per cent). A small number of mesenteric lymph nodes examined all yielded the bovine type of Bacillus tuberculosis. In no case was the bovine bacillus encountered outside the tonsils or the cervical or mesenteric lymph nodes. A discussion is included on the not infrequent failure of the guinea-pig inoculation test for the recovery of Bacillus tuberculosis.

**46**: 163-182 (March 5) 1932

*Gaseous Abdominal Abscesses. P. Mocquot.—p. 167.

**Gaseous Abdominal Abscesses.**—Mocquot reports six cases of gaseous abdominal abscesses to show the clinical aspects and the diagnostic difficulties they may present. Two of the cases concern abscesses of the upper part of the abdomen, especially the subhepatic region; three, of appendicular origin, were located in the right iliac fossa and the umbilical region; the sixth was in the pelvis, ascending into the hypogastric region and the left iliac fossa. What makes diagnosis difficult in cases of this kind is that, with a clinical history and general symptoms pointing to an inflammatory process, one can find none of the physical signs of a localized abdominal abscess; there is no doughiness, and the hardness so characteristic of suppuration, as well as dulness on percussion, is wholly lacking. The abdomen is sometimes considerably distended; the meteorism is so pronounced it may cause compression of the chest and dyspnea and one finds a tympanitic resonance everywhere, which one is tempted to attribute to distention of the intestinal loops. Sometimes a pyogaseous collection, if contained in a well circumscribed cavity, possesses a definite perceptible contour, which would make one think of intestinal occlusion if the general symptoms did not contradict that diagnosis. While the customary signs of localization of an intra-abdominal suppuration (indicated by the general symptoms) are missing, there are a few symptoms to put one on the right track. The tympanites is not always uniform, the bulging is often more perceptible at the site of the abscess, there is sometimes a more pronounced tension of the wall in that region, and the resonance is more tympanitic than in the rest of the abdomen. The author thinks palpation of the anterior wall of the abdomen is deceiving and stresses the importance of bimanual palpation to acquire a precise idea of an abnormal tension, an increase in thickness, and a fulness, which is the sign of a gaseous collection. Above all, it is necessary to have the gaseous abscess in mind to arrive at a correct interpretation of seemingly contradictory symptoms. The value of hematologic and especially roentgenologic examinations is mentioned. The author also discusses the source of the gas filling the cavity of the abscess.

### Gazette des Hôpitaux, Paris

**105**: 334-348 (March 5) 1932

Hypophyseal Syndromes. C. Dejean.—p. 337.
*Spontaneous Pleural Epilepsy: Case. R. Mignot and L. Couderc.—p. 343.

**Spontaneous Pleural Epilepsy.**—Mignot and Couderc state that epileptic crises of pleural and so-called spontaneous origin (independent of any intervention in the pleura) are rare, and they report the case of a woman who died following an epileptiform crisis occurring in the course of a serofibrinous pleurisy, which was apyretic and not recognized; no medical intervention on the pleura determined the convulsive phenomena. A woman, aged 49, was interned in an asylum because she suffered from hallucinations. No organic disturbances were noted, with the exception, perhaps, of a small quantity of pus in the urine. A condition of stupor soon developed, confining the patient to bed. During occasional lucid intervals, she complained of terrifying hallucinations. Death resulted from an epileptiform crisis about fifteen months after entry into the asylum. A week before death, zoopsic hallucinations and increased agitation were observed; no symptoms of organic disturbance were noted, and the patient did not cough or express any complaint and did not have a fever. Stertorous respiration was noticed the night preceding the crisis and again during the fatal crisis. The aspect of the brain and meninges at necropsy was normal, and there were no pathologic changes in the abdominal viscera, but opening of the thorax revealed a large serous effusion in the left plueral cavity; the lung was reduced to an atelectatic stump, firmly fixed to the wall by adhesions.

Return Circulation and Gestation. C. Laubry, E. Lévy-Solal and A. Tzanck.—p. 321.
*Interesting Form of Breast Cancer: Degenerated Adenoma. A. Schwartz.—p. 323.

**Form of Breast Cancer: Degenerated Adenoma.**—Schwartz reports the case of a woman who came to him with a tumor of the breast, the symptoms of which resembled those of a fibro-adenoma but were not quite as marked as those of a true fibro-adenoma. The tumor mass, which was the size of a small orange, was movable, but the mobility was not as extensive as in a normal fibro-adenoma; also the movement of the skin over the tumor was not absolutely free, a beginning adherence being found. These two characteristics determined the diagnosis of degenerated fibro-adenoma, which was confirmed by intervention. The case report is followed by a discussion of the clinical aspects which a fibro-adenoma may present. In certain cases the degenerated fibro-adenoma, while assuming entirely the appearance of a cancer, keeps for a long time its definitely circumscribed character, which permits it to be differentiated from pure cancer although leaving no doubt as to its neoplastic nature. In other cases, the degeneration exists but nothing permits one to suspect it. The author here warns against assuring a patient with certainty that a tumor is benign. When a fibro-adenoma is removed, the clinician should tell the patient that a histologic examination will be made to confirm the absence of suggestive cells; if the examination reveals neoplastic degeneration and amputation of the breast is necessary, the patient, already forewarned, may be told that a few suggestive cells were found and while the tumor is, on the whole, benign, a more extensive operation will be necessary. Between the two types of clinical aspects described stands the case in which a doubt exists. In these cases the tumor should be removed under local anesthesia and an immediate histologic examination undertaken. The author considers it bad to remove such a tumor and a few days later amputate the breast, as it may lead to an early and rapid generalization of the neoplasm. He advises above all to try to make a clinical diagnosis of the malignant change so that one can perform the necessary operation immediately.

*External Strangulation of Uterus. S. W. Kissine.—p. 194.

**External Strangulation of Uterus.**—Kissine reports an unusual case of external strangulation of the uterus associated with its prolapse and discusses the literature. The patient was a woman, aged 70, who had been suffering from occasional prolapse of the uterus for eleven years. Reduction of the uterus had always been accomplished by the patient, in horizontal position, without difficulty. On the occasion when the author was called, the uterus had again prolapsed but could not be reduced by the patient. It protruded from the genital opening like a tumor one and a half times the size of a fist. The external orifice of the cervix inclined toward the perineum. The prolapsed tissue, which seemed wedged in place, was reduced by the author only after repeated attempts and the application of a certain amount of physical force. Bimanual examination immediately after the reduction revealed a firm, slightly enlarged uterus with an elongated cervix and to the left of it a round, hard, mobile tumor the size of an apple, apparently associated with the ovary. The author considers it unlikely that the resistance of the uterus to reduction was due to edema, as it had been reduced easily a short time previously, or to inversion, because of the external aspect and the presence of the cervical orifice, but attributes it to the tumor. He thinks it probable that the tumor usually remained in the abdominal cavity but in this instance was forced out by considerable intra-abdominal pressure or pulled out by the utero-ovarian ligament during the descent of the uterus, so that the ovarian tumor was in front of the pubic arch, and the uterus, in anteflexion, was in front of the tumor. The two organs could not be returned to the interior together, and it was necessary to return the ovary before the uterus could be reduced.

Congenital Xanthelomatous Angiolymphangioma of Gingival Margin. J. M. Jorge, S. I. Nudelman and M. Gringauz.—p. 190.

**Vertebral and Costal Osteomyelitis in Early Infancy.**—Gamboa and Montarcé state that the localization of osteomyelitis in the vertebrae is rare and indicates a grave form of the disease. The lumbar vertebrae are the most frequently involved, but there is a possibility of development of the disease in any other vertebra. The seriousness of the disease bears a relation to the seat of localization of the osteomyelitic lesion, either in the bodies of the vertebrae or in the vertebral arches (more grave when involving the bodies of the vertebrae than when involving the vertebral arches), and not with its segmental localization (in the cervical, thoracic or lumbar segments of the vertebral column). The involved vertebrae, surrounded by blood and pus, undergoes a process of destruction caused by the infiltration of the spongy tissue with pus. The symptoms are in relation to the intensity of the pyemic infection, the irritation of the spinal nerves, the spinal cord involvement and the general condition of the patient. In rare cases the osteomyelitic abscess, instead of following an evolution of exteriorization, progresses toward the spinal canal, thus giving origin to the appearance of symptoms of medullary compression, such as paraplegia, hemiplegia or relaxation of the sphincters. In this case the abscess may rupture into the spinal canal. The meningeal reaction in this type of osteomyelitis is grave, and usually death occurs. In subacute forms the pyemic infection is attenuated, the meningeal reactions are less severe, and if the patients are properly treated, about 54 per cent of recoveries is obtained. In acute cases the treatment is solely surgical. It is advisable to remove and drain the septic foci as soon as possible. In subacute cases the evacuation of the pus, by a puncture of the abscess, the administration of pyogenic vaccines, the immobilization of the spine in a cast, and the proper treatment to improve the patient's general condition, give good results. The authors report a case of vertebral and costal osteomyelitis in an infant, aged 40 days. The patient presented five days after birth a tumor on the right hip bone (probably a benign hematoma caused by either obstetric or postpartum trauma). Some days later he presented the symptoms of an acute infection and a gibbosity of the thoracic segment of the vertebral column which proved to be an osteomyelitic abscess involving the sixth, seventh and eighth thoracic vertebrae with extension of the lesion to the heads of the sixth, seventh and eighth ribs. The abscess was situated in the vertebrae and nevertheless the infection and the meningeal reactions (opisthotonos) were of a subacute type. The roentgen examination showed that a process of bone healing of the involved vertebrae and heads of the ribs was produced under the influence of the treatment. From the pus obtained by puncture of the abscess of the hip bone, in this case, streptococci were identified. The authors believe that, in their case, an umbilical infection may have been the portal of entry of the infection. The passage of pyogenic bacteria into the blood may have caused the infection of the tumor of the hip bone, followed by the development of the vertebral osteomyelitic lesion. The gibbosity disappeared and the patient recovered.

**Treatment of Malignant Tumors with Radium and Surgery.**—Láng advocates the use of radium in such localizations and in those stages of cancers in which surgical interventions are impossible or will give less favorable results. He considers radium therapy especially helpful in cancers of the oral cavity. The results he obtained with radium in these cases are such that surgical interventions involving considerable mutilation are no longer justified. However, not only in cancers of the oral cavity but also in those of the nasal cavity, of the larynx and of the palate, that is, in regions in which surgical interventions are extremely dangerous and difficult, radium produces favorable results. For cancers of the face and the lips, radium is superior because of its more favorable cosmetic effects. The author emphasizes that he obtained his favorable results with comparatively small quantities of radium. He thinks that the experienced surgeon can use radium to greater advantage than the irradiation specialist, for the reason that in many cases the surgeon can place the substance more favorably.

**Diagnosis and Treatment of Chronic Abscesses of Bones.**—Kment points out that chronic abscess of the bone may be mistaken for such conditions as articular rheumatism, syphilis, gout or tumors, but he thinks that such erroneous diagnoses can be avoided if careful attention is given to the anamnesis. After mentioning the chief symptoms, he describes the characteristic roentgenogram. Especially in the metaphysis of the long bones, such as the tibia and the femur, the abscess cavity appears as a spherical or oval, sharply outlined area of decreased density with greater density of the surrounding bone tissues. On the basis of several case reports, the author then shows that the term "chronic abscess of the bone" as denoting a separate disease entity is not justified but that this condition is a form of the hematogenic, chronic, suppurative osteomyelitis without abscess formation. In regard to the treatment, he states that he has abandoned the former practice of a wide opening of the cavity of the bone in such abscesses, for it involves certain difficulties on account of the nearness of the joint, in that usually there remains a funnel-shaped opening, which it is impossible to obliterate by muscle flaps, since there is generally little muscular tissue in the region of the abscess. For this reason the author has for years employed a half-fluid iodoform preparation as a filling for the abscess cavity. The filling is introduced after the abscess cavity has been evacuated and then dried by prolonged tamponade. It is essential that no air filled spaces remain but that the filling close the entire cavity. Following the filling the periosteum is carefully closed over the drill canal and the soft parts are sutured in layers. The wound heals by primary intention, but in some instances fistulas develop after the operation. These, however, usually do not originate in the bony cavity but rather are due to the particles of iodoform that during the introduction of the preparation entered the soft tissues. A later roentgenoscopy nearly always revealed that the cavity was completely filled.

**Endocarditis Caused by Anaerobic Streptococci.**—Bingold points out that although the pathogenic character of anaerobic streptococci has been established, it was not known until recent years that they may cause endocarditis. Because of the peculiar pathogenesis of such cases and because of certain characteristic aspects, the author gives the detailed histories of two cases that he observed recently and short reviews of other cases that had been reported before. In the summary he mentions the following as the most characteristic aspects of endocarditis caused by anaerobic streptococci: 1. The disease always takes a fatal course. 2. The slight pathologic changes on the cardiac valves and on the other portions of the heart do not correspond to this unfavorable prognosis. The lesions do not have an ulcerous character. 3. Compared with endocarditis lenta, the course is more acute or subacute. 4. In contradistinction to the endocarditis caused by aerobic organisms (staphylococci and streptococci), in which, as a rule, there exists a continuous fever, the endocarditis caused by anaerobic streptococci is characterized by frequent attacks of chills. 5. In spite of frequently observed continuous bacteremia, there is an almost complete lack of metastases, in contrast to the septic endocarditis caused by streptococci and staphylococci. Emboli are found almost exclusively in the lungs. 6. Ports of entry of the anaerobic organism are primarily the female genitalia, the tonsils, the middle ear and the intestinal tract. 7. The occurrence of numerous anaerobic streptococci in the blood culture (outside of the attacks of chills) makes the diagnosis of anaerobic streptococcic endocarditis possible during life, even when heart murmurs are absent. The treatment may be the same as in other forms of septic endocarditis, but in all the cases that came under the author's observation it failed.

**Significance of Lactic Acid Content of Vagina.**—Traube and Weber call attention to the fact that the vaginal secretion has an acid reaction and that the acid content consists primarily of lactic acid. It has been determined that the acidity varies in different women and also that it varies in the same woman at different times of the menstrual cycle. It is highest during menstruation and lowest midway between two menstrual periods. It has also been found that spermatozoa are impaired by a high concentration of lactic acid. The latter factor makes it understandable why in sterile women, with a high acid content of the vagina, conception has been facilitated by vaginal douches with alkaline solutions. On the other hand, conception can be prevented by introduction of substances containing lactic acid or by irrigation with lactic acid or acetic acid solutions. The injurious effect of lactic acid on the spermatozoa is explained by colloidochemical processes. Acid solutions, especially lactic acid solutions, cause swelling of lyophil colloids, and since spermatozoa consist mainly of lyophil colloids, it is understandable that the swelling action of lactic acid impairs their functions.

**Postoperative Circulatory Therapy.**—In discussing postoperative shock or collapse, von Bergmann does not refer only to the collapse that develops during the anesthesia or immediately after the intervention, but even more to those threatening conditions that develop on the following day or even several days later, and also to the usually less harmful conditions that develop after the patient first gets up again, such as attacks of fainting, cold extremities and general weakness. He shows that these conditions are not caused by a cardiac weakness but are primarily the result of a disturbance in the distribution of the blood. The decomposition of protein that takes place after surgical interventions, and the resulting autointoxication, influence the peripheral circulation in such a way that large quantities of blood are retained in the periphery, and the amount of blood received by the heart is not adequate. It should therefore be the object of the treatment to empty the peripheral blood depots. The so-called autotransfusion by bandaging the extremities is helpful to some extent. However, it should be considered that neither this transfusion nor transfusion from a donor can be of much help as long as a large portion of the vessels are pathologically dilated. It has been proved that camphor and camphor-like substances are helpful for this condition and that strychnine and injections of caffeine are the remedies of choice. The author thinks that in life-endangering conditions several of the remedies can be tried at intervals of from two to three hours. The use of digitalis he considers necessary only when the cardiac action fails, and the prophylactic application of digitalis preparatory to an operation he considers as entirely ineffective.

*Calcium and Potassium Contents of Blood Serum and Ultrafiltrability of These Minerals in Renal Insufficiency. H. G. Scholtz.—p. 472.
*Value of Alimentary Galactosuria in Diagnosis of Diseases of Liver. W. Hochheim and B. Misske.—p. 511.
*Therapeutic Modification of Mineral Composition of Blood in Tetany. H. G. Scholtz.—p. 539.

**Calcium and Potassium Contents of Blood Serum.**—Scholtz made tests on the calcium and potassium contents of the serum of patients with renal insufficiency and also considered the ultrafiltrable portions. In some cases of contracted kidney and of acute nephritis, he detected low values of calcium in the serum. In the majority of cases of contracted kidney, the ultrafiltrable portion of calcium was reduced and the percental content of colloidal calcium was increased. This manifestation has no relation to the amount of the rest nitrogen and does not increase the predisposition to spasm, but it is assumed that it has some connection with changes in the protein bodies. An increased potassium content of the serum was found, especially in anuria. When the potassium content of the serum is increased, the potassium appears largely in the colloidal form. The ratio of calcium and potassium in renal insufficiency has no apparent relationship to the clinical manifestations.

**Alimentary Galactosuria in Diseases of Live**
Hochheim and Misske show that the clinical value of P

galactose test has not been definitely demonstrated as yet. They think that the galactose test can have value only if it can be done in a simple manner and if it helps in clearing the diagnosis in questionable cases. Blood sugar curves have only theoretical value. The authors performed the test on 225 patients, of whom 100 had hepatic or biliary disorders and the other 125 had various other disorders. It was found that in severe toxic icterus the test gives usually, but not always, a positive reaction. However, in mild cases of toxic icterus the test fails, which of course reduces its diagnostic value considerably. The test was plainly positive in a case of Addison's disease.

**Therapeutic Modification of Mineral Composition of Blood in Tetany.**—Scholtz describes changes that he observed in the calcium, potassium, sodium and phosphorus pentoxide contents of the serum, and changes in the physical conditions of these minerals during idiopathic tetany, while the patient underwent treatment with calcium, with parathyroidal preparations or with ammonium chloride. Administration of small quantities of calcium did not increase the calcium values of the serum, but the same doses of calcium caused a noticeable hypercalcemia in normal persons. By administration of large doses, the calcium content of the serum of the patient with tetany became nearly normal and there was also an increase in the ultrafiltrable calcium. However, the ratio of the colloidal to the truly solute portion of calcium remained, as before the treatment, in favor of the colloidal portion. Besides this there developed during medication with large quantities of calcium a considerable increase in the phosphate content of the serum, which otherwise was only slightly increased, and the increase was entirely in colloidal phosphorus. The parathyroid hormone modified the ultrafiltrable calcium and the clinical manifestations even before it increased the calcium content of the serum. When doses of calcium, which alone did not effect an increase in the calcium content of the serum, were administered simultaneously with the parathyroid hormone, there was an increase in the calcium content of the serum and the solubility conditions were normal. Accordingly it is assumed that the parathyroid hormone effects a mobilization of calcium in the tissues and that it perhaps also influences the solubility conditions of the calcium. Ammonium chloride, when administered alone, caused a considerable reduction in the calcium content of the serum but also increased its solubility. When administered together with calcium, the ammonium chloride produced apparently normal calcium conditions in the serum. A characteristic behavior of the potassium values of the serum was not noticeable. The sodium values were normal.

**Changes in Function of Liver During Pregnancy.**—Kaufmann, in testing the various functions of the liver during normal pregnancy, found a high percentage of abnormalities. These changes are characterized by a deficiency in the carbohydrate assimilation of the liver, a deficiency in the elimination of administered bilirubin, and a reduced glycogen content of the liver. The author then discusses whether this abnormal reaction is a weakness or is a partial manifestation of the changes in the entire metabolism. He thinks that the changes in the metabolism overtax the function of the liver. As a result of this the liver does not have a sufficient reserve power to cope with tolerance tests. The abnormal course of the functional tests of the liver is thus a result of the metabolic changes that develop during pregnancy. But one should not designate this course of the reaction as "pathologic." However, that the great functional requirements of the liver may also produce a weakness was proved by postpuerperal after-examinations on two women. In both of them, functional tests of the liver revealed disturbances as late as six months after confinement, and neither of the women nursed her infant. Moreover, a careful anamnesis gave no indications that a disturbance of the liver had existed before the pregnancy. It is possible that these cases are exceptions, yet even in that case it can be concluded that a normal pregnancy may be the cause of a latent hepatopathy.

**Significance of Heavy Metals for Treatment of Anemia.**—Following a review of the literature, Schultze reports his own studies on rats. He emphasizes that in these studies two factors have to be kept apart: (1) the formation of hemoglobin, which according to the present status of knowledge is possible only if iron is present, but which is probably catalytically influenced by other metals, and (2) the formation of erythrocytes. It was his object to determine whether synthesis of hemoglobin and formation of erythrocytes are separate functions, and also whether the elements to which a catalytic effect is ascribed influence the hematopoietic system without the presence of iron. His tests were made with nickel, cobalt, copper and iron. He found that whereas iron influences both the hemoglobin synthesis and the formation of erythrocytes, the other elements—cobalt, nickel and copper—stimulate the erythropoiesis without being able to influence the hemoglobin synthesis in the absence of iron. The catalytic effect of the various metals is due to the fact that they exert a formative stimulation on the red bone marrow. The effect of liver therapy in the treatment of anemia is probably largely due to the action of copper.

**Treatment of Posttonsillitic Pyemia.**—Melchior thinks that the pyemic form of tonsillitis and the possibility of influencing it by ligation of the jugular vein is not sufficiently known by the general practitioner, who usually is consulted for such cases. The author admits that there are some forms that begin with chills and yet take a favorable course, but he advises that if the chills recur, and the temperature is unusually high so that the local processes do not provide a sufficient explanation, and if primary diseases of the blood such as agranulocytosis and leukemia can be excluded, ligation of the jugular vein should be resorted to, before it is too late. Two cases proved to him the significance of this procedure. In one patient the condition had progressed too far for treatment, but in the other the ligation led to recovery. The author emphasizes that the ligation does not have to be postponed until the vein has become involved; that is, after thrombosis has set in. He does not agree with those throat specialists who advise removal of the involved tonsil at this time. He considers tonsillectomy in the still infected region neither necessary nor helpful, and in some cases dangerous.

**Changes in Conception of Nature of Vitamins.**—Abderhalden states that formerly vitamins were considered as preformed substances that were contained in certain foods. In recent times, observations have been reported which make it appear probable that the substances contained in the foods do not represent the products that exert the vitamin action but rather develop from them, following resorption in certain tissues. If this assumption is true, the effective substances that develop from the "provitamins" could be compared with the hormones. The author's object in calling attention to this was to encourage investigations as to whether vitamins are formed in the organisms out of subtances contained in certain foods. If it should be shown that the real vitamins are formed beyond the intestinal wall, research would have new problems to solve, such as what types of cells are necessary for the different vitamins. The author is convinced that such studies would solve many problems in the action of vitamins, which as yet are not understood.

**Regulation of Insulin Production.**—Grafe shows that the regulatory system of insulin production is much more complicated than it appears at first. According to the law of the double or threefold security, which obtains in nearly all important metabolic processes, there are at least three interacting mechanisms. The superior and the one with the most delicate function is the central nervous system. There is probably a center in the thalamus, which responds directly to the fluctuations in the blood sugar, and which according to need sends its impulses by way of the vagus directly to the islands of Langerhans. In addition to this the sugar, like a hormone, also acts directly on the production centers of insulin. Fluctuations in the activity of the suprarenals likewise act directly on the insulin production. Whether the external secretion of the pancreas also exerts a regulatory influence on the insulin production has not been definitely established as yet, and it is considered improbable.

Local Blood Picture During Tuberculosis in Children. Gertrud Kehling.—p. 239.
Pathogenesis of Functional Albuminuria. H. Lewitus and W. Rabinowitsch.—p. 250.

**Influence of Rickets on Development of Jaws and Teeth.**—Kirsch and Rosenbaum examined twenty children during the nursling period and also during the period following for the presence of rachitic symptoms but never detected such symptoms, and during the period of dentition the children were also examined by dentists. Control examinations were made on children who had passed through severe rickets and also on a small group, who presumably had had a mild form of rickets. On the basis of these studies the authors reach the following conclusions: 1. Deformities of the jaws are found almost exclusively in children that have passed through a severe or a mild form of rickets. 2. Caries of the deciduous teeth is found frequently in children who are entirely free from rickets; however, in children who have passed through severe rickets the carious destruction of the deciduous teeth is still more pronounced. 3. Caries of the teeth of the second dentition is comparatively rare in children who have been free from rickets, but in those who had had rickets it was noted in 50 per cent of the cases. 4. Delayed dentition (appearance of the first deciduous tooth later than the eighth month) is also found in children without rickets.

**Acid-Base Economy in Children.**—In rachitic nurslings and in rachitic premature infants, the Hottingers observed a considerable increase in the elimination of organic acids, which reached normal levels again on recovery. Ammonia and the amino-acids showed a similar behavior. In the earliest stage of rickets there is no increase in the elimination of the organic acids, and for this reason the manifestation is of no value for the early diagnosis of rickets. If in the course of rickets a tetany develops, the erstwhile increased elimination decreases to normal levels or at least shows a slight reduction. Test on a healthy gravida during the seventh month of pregnancy revealed that the elimination of organic acids was normal. The new-born, who had icterus, showed a low elimination during the period of loss of weight. During dyspepsias that do not cause great changes in the metabolism there is a decreased elimination of organic acids, whereas during dyspepsias with atrophy there is an increased elimination. Likewise caused by secondary atrophy are the high values of organic acids in cases of pylorospasm, for in the early stages of this condition the elimination of organic acids is not increased. In exudative diathesis, the organic acid content of the urine fluctuates considerably. A child with diabetes eliminated enormous quantities of organic acids not only as long as acetone bodies were demonstrable in the urine but also after diacetic acid, acetone and sugar had disappeared from the urine. The authors also studied the influence of exogenic factors on the elimination of organic acids, such as irradiation with the quartz lamp, restriction of water intake, feeding with cow's milk instead of breast milk, and increased intake of proteins, fats or carbohydrates.

**Influence of Diuretics on Impaired Heart.**—Donath states that although the use of diuretics is of great value in the therapy of cardiac disorders, especially in conditions of decompensation, there are also cases in which potent diuretics cause undesirable complications. The author illustrates this by several case histories. On the basis of his observations, he advises one to strengthen the heart by medication with digitalis previous to employing a potent diuretic, or to combine the administration of the diuretic with strophanthin. During the time the diuretic is active, all bodily and psychic exertion should be avoided by the patient. If possible, the patient should be kept in bed for twenty-four hours. When not absolutely necessary, the use of potent diuretics should be avoided and those acting more slowly should be used. The author further suggests that in some cases the heart can be excluded from the diuretic work by resorting to surgical procedures, such as puncture in hydrothorax and in ascites.

**Demonstration of Tubercle Bacilli in Blood Stream in Skin Diseases.**—Konrad relates the results that have been obtained with Löwenstein's culture method in a dermatologic clinic in Vienna. His report covers a period of approximately two years. Löwenstein's culture method was employed mainly on blood specimens from patients with true tuberculosis of the skin, with tuberculids and with lupus erythematosus, but also in patients with so-called rheumatic dermatoses such as e thema exudativum multiforme, erythema nodosum and pura rheumatica, and finally in a group of persons that served as controls. Tests on fifty-two persons gave positive results in twenty-two instances. In tuberculous diseases of the skin, the blood culture was found positive in 50 per cent of the cases. The percentage of positive reactions was especially high in lupus erythematosus. That the tests are more often positive during spring and summer than during fall and winter was noticeable during 1930 and 1931; but this was not so noticeable during 1931 and 1932. The positive outcome of the culture test in one case each of lymphatic leukemia and mycosis fungoides indicates the necessity of further investigation.

**Subcutaneous Rupture of Pectoralis Major.**—Borchers and Tontscheff relate the clinical history of a miner, aged 50, who, while lifting a heavy load, was accidentally pushed from the back so that the tensely contracted pectoralis major was forced against the edge of a cart. The man felt a severe pain on the left side of the chest, and on the following day marked swelling had developed, which was ascribed to a contusion of a rib. Several other physicians, who examined the patient, likewise failed to recognize the injury of the muscle, and when after eighteen months the man had not yet regained the full use of his arm, he came under the authors' observation. He complained of a weakness in the left arm and it was noticed that the left side of the chest was flatter. When the patient was told to try to adduct the arm while the examiner held it, it was noted that the lower two thirds of the muscle, namely, the pars abdominalis and the pars sternocostalis, appeared as if rolled together, and between this elevation and the upper arm there was a depression. This proved that the lower two thirds of the pectoralis had lost their connection with the tendinous attachment on the upper arm, whereas the upper third of the muscle, the pars clavicularis, had not been injured. Thus, if all three portions of the muscle are taken as a whole, there was a tear into the muscle. A careful review of the literature revealed that only ten similar cases have been reported, but it is noteworthy that a tearing of the muscle is more likely than a detachment of the tendon from the upper arm. In regard to the treatment, the authors state that in the reported case active treatment was not resorted to, but they think that in younger persons it might be attempted to reunite the muscle by a suture or even resort to plastic repair. In the conclusion, the main symptoms of the tearing of the pectoralis major are once more summarized.

Hematin Reaction in Extra-Uterine Pregnancy. S. Wolowa.—p. 812.
Experimental Biologic Interruption of Pregnancy. W. K. Tschaikowsky.—p. 815.

**Roentgenologic Demonstration of Hydatidiform Mole.**—According to Bortini, the early diagnosis of hydatidiform mole is often difficult since it has to be based on symptoms that are also found in other conditions. Absolutely certain is the diagnosis only after vesicles have been discharged. Following enumeration of the different symptoms on which the diagnosis is usually based, the author describes his method of roentgenologic demonstration. He points out that after three months a pregnancy can be recognized by means of roentgenography. If at this period repeated roentgenographies do not show portions of a fetus, it is permissible to resort to hysterography by introducing a contrast medium. The author employed an iodized oil and found the resulting roentgenologic picture so characteristic for a hydatidiform mole that it could not be mistaken for other conditions, such as cancer or myoma. The iodized oil enters between the vesicles of the mole and thus the roentgenogram has irregular outlines; it shows zones of various sizes and of various degrees of density and dark irregular stripes. In nine cases the author could confirm the diagnosis of hydatidiform mole with this method and in one instance he could base his diagnosis on this method of examination. He stresses that it is absolutely necessary to precede the injection of the contrast medium by a simple roentgenoscopy, so as to make sure that a normal pregnancy is not interfered with.

**Investigation of Female Vertebral Column in Relation to Gynecologic Backache.**—On the basis of former studies, Uebermuth reasons that gynecologic backache is sometimes the result of changes in the intervertebral disks. To find supporting evidence for this assumption, he made roentgenologic examinations of fifty women who complained of backache. He found that degenerative changes in the intervertebral disks can be recognized indirectly from certain conditions of the vertebrae. As indications he considers the following: a basin-shaped depression of the caudal and cranial vertebral surfaces, also sclerotization of these surfaces, and "transverse areas of hardening" underneath the terminal bony plate of the vertebral body (spongiosa plates). The latter manifestations indicate that the organism tends to replace the lost elasticity of the intervertebral disks by a greater solidity. The secondary manifestations in the bone develop quite early; namely, in the third decade of life. This corresponds to the early manifestations of wear and of age degeneration in the intervertebral disks. The circumscribed areas of increased density in the substantia spongiosa underneath the terminal bony plates may be interpreted as calcified cartilaginous nodules or as circumscribed spongiosa plates. These manifestations have clinical significance since they indicate degeneration of the intervertebral disks. During the progressive stage the changes cause disturbances in the static mechanical function of the vertebral column, which may result in backaches. The author considers overburdening of the female vertebral column during pregnancy as one of the main causes of the disturbances.

**Air Emboli During Insufflation in Artificial Pneumothorax.**—Of the four cases reported by Szczepański, severe symptoms of embolism occurred in three. In one case the result was fatal. In each of the three severe cases the author had to deal with a pneumothorax complicated by adhesions; embolism appeared during complemental insufflation, not during the original operation. Most probably, in the fatal case, death was caused by plugging of the coronary vessels, because cerebral symptoms were absent. The second case was the only one that occurred during the original insufflation. The symptoms were slight. In the third case, symptoms of embolism appeared after the operation was completed. In this and in the fourth case there were cerebral symptoms, characterized especially by onset of temporary blindness, without, however, any recognizable changes in the ocular fundus. According to the author's experience, the danger of embolism is imminent in cases with partial pneumothorax, complicated by adhesions. For this reason, he adds, it is best to avoid high pressures, which tend to rupture the adhesions and to open the vessels.

Case of Cysticercosis of Central Nervous System and Skin. B. Stepień and M. Grzybowski.—p. 321.

**Salicylic Acid in Allergic Skin Diseases.**—Among the allergic skin diseases there is a certain form of eruption, called by Rost "Spätexsudatives Ekzematoid." In this disease the ability of the blood to neutralize or bind salicylic acid is diminished and the patients are hypersensitive to salicylates. Chylewski completed a research in fifty-seven cases for the purpose of establishing in which of the allergic skin diseases minimal quantities of salicylic acid are neutralized, as compared with normal blood, and with other dermatoses. The author noted the quantities of free salicylic acid per milligram of ether extract of blood, in the following groups: (1) Rost's eczematoid; (2) urticaria; (3) strophulus; (4) tuberculosis of the skin; (5) secondary syphilis; (6) control, and (7-9) nonallergic: mycotic, staphylococcic and streptococcic. The results are: In urticaria perstans the blood binds or neutralizes minimal quantities of salicylic acid. In nonallergic dermatoses the ability of the blood to neutralize salicylic acid is not diminished but increased, which is, in the author's opinion, a new observation.

*Specificity and Practical Value of Davis Cancer Reaction. O. Gubanova. —p. 1017.

**Immunity Against Bacteria of Gas Gangrene.**—Velikanov and Kavenoki found that when they cultivated Clostridium oedematiens under strict anaerobic conditions the toxicity was increased so that 0.001 cc. was fatal for rabbits. When cultures were treated with a 0.5 per cent solution of formaldehyde and incubated at 37 C. for thirty days, the cultures became avirulent and harmless. Cultures so treated were used for immunization of animals. Rabbits were immunized with toxoid and mixtures of equal quantities of toxoid and vaccine; doses of 2, 3 and 5 cc. were injected intramuscularly at intervals of ten days; the animals were bled from fifteen to twenty-five days after the last injection, but titrations were not made until one or two months after bleeding. After immunization, rabbits tolerated easily 2, 5 and 10 lethal doses of culture. The serums examined two months after storage and diluted 1:5 neutralized two lethal doses of a three day culture of C. oedematiens. Horses were immunized with progressively increased doses, beginning with 25 cc. of a formaldehyde treated culture. The horses were bled eighty days after the first injection. The horse serum diluted 1:8,000 was found to neutralize 2 lethal doses of a three day culture of C. oedematiens. The serum stored for one year under different conditions still retained its protective power in a 1:1,000 dilution. The serum may prove beneficial in therapy.

**Practical Value of Davis Cancer Reaction.**—Gubanova states that her survey of the literature indicates a renewed interest in the Davis reaction as an adjuvant in the diagnosis of cancer. During her study, careful attention was paid to the technic. The test as first described by Davis required a slightly acid reaction of the urine (10 cc. of hydrochloric acid was added to 100 cc. of urine, the mixture was warmed to boiling, cooled, and 30 cc. of water-free ether added, the bottle was stoppered and placed in a cool dark place and the reaction was read in twenty-four hours). The author found that twenty-four hour or two to four hour old samples of urine gave negative Davis reactions even when acidified and with a specific gravity not less than 1.010, whereas freshly voided samples from the same patients gave strongly positive reactions even when the urine had a neutral reaction. Examinations for protein, sugar, acetone, urobilin, indican, blood, bile pigments, and the diazo reaction did not demonstrate any relationship to the Davis test. Boiling of the urine did not affect the results of the reaction. Care was taken to place the urine-ether suspension directly in a dark cool place, since light itself always gives a pink color to the ether. In reading the test, both the color of the ether phase and the sediment that came down after heating was noted. The reaction was considered negative when the ether phase after twenty-four hours was colorless and the precipitate was brown or dark brown; questionable, when the ether was orange and the precipitate brown; slightly positive, when the ether and the precipitate were rose colored; distinctly positive, when the ether was raspberry red and the precipitate raspberry colored; and strongly positive, when both the ether and the precipitate assumed a raspberry red. Among thirty-five patients with malignant neoplasms, thirty-two had positive Davis reactions without regard to the localization, while one with sarcoma and two with hypernephroma had negative reactions. The author also examined 160 patients without malignant tumors. The Davis test was found negative in one group of thirty patients with nonspecific and functional disturbances of the gastro-intestinal tract; negative in all but two (slightly positive in one instance of tuberculosis and another of lobar pneumonia) in a group of twenty-eight patients with diseases characterized by tissue breakdown and large quantities of protein breakdown products, as in tuberculosis, various abscesses, nephritis, gangrene; negative in two instances of cardiac decompensation; negative in twenty-eight cases of endocrine disturbance (the menstrual period did not influence the reaction); negative in eight instances of renal disturbance and also in another group of hepatic disturbance with large erythrocyte breakdown; in ulcer of the stomach and duodenum the reaction was negative; however, a group of twenty patients with circulatory disturbance, five with pernicious anemia and two with myeloid leukemia, had strongly positive Davis reactions; and among five patients with acute neurasthenia, three had distinctly positive Davis reactions. The reaction was negative in six instances of essential hypertonia and diabetes mellitus and in four instances of visceral syphilis, while two persons in a group of apparently healthy individuals gave positive reactions. It was noted that the reactions were similar in intensity and color of the ether phase and the precipitate in the cancer, pernicious anemia, myeloid leukemia, several instances of tapeworm infection, in women in the first month of pregnancy, and in the apparently healthy individuals.

**Lymphogranulomatosis: Disease of Paltauf-Sternberg.**—Oks states that the clinical course of lymphogranulomatosis is in favor of an infectious process. Statistics of this disease are few; the percentage is larger for men than for women; there are no age limits, although the majority of cases seem to occur in the age group 30 to 40. An accurate diagnosis of lymphogranulomatosis is possible only when the progress of the generalized process is typical and when the usual symptoms are present: enlargement of the lymph nodes and spleen, characteristic recurring elevation of temperature, and changes in the blood. Accurate diagnosis in localized lymphogranulomatosis is infrequent (thirteen cases were diagnosed accurately in a group of forty-seven); mistakes are generally due to the consideration of the disease as a systemic disease of the lymphatic apparatus only, and lack of recognition of the primary stages of the disease. It is now known that lymphogranulomatosis is a disease not only of the lymphatic apparatus but also of organs free from lymphoid tissue (nervous, bone). The large area of incidence leads to confusion with malignant neoplasms. The experimental, bacteriologic study of the blood is valuable in differential diagnosis. The diazo reaction usually appears in this disease. The author suggests the classification of glandular, mediastinal, splenomegalic, gastric, intestinal, pulmonary, dermal (mycosis fungoides), osteoperiosteal lymphogranulomatosis. Mistakes in diagnosis may be decreased if (1) in every case of glandular disease histologic and biopsy examinations are made, if (2) microscopic examinations are made in tumors and ulcers of the stomach and colon, and if (3) in cases of sepsis, typhoid, and miliary tuberculosis, experimental and bacteriologic examinations are made of the blood.

**Two Aspects of Cardiac Decompensation in Relation to General Blood Circulation.**—Basok and Shesterikova state that blood circulation in the organism is regulated not only by rhythmic action of the heart but by the whole vascular system. The exchange of fluids and electrolytes between the blood and the body tissues due to the blood circulation is influenced by blood pressure, rate of flow, and quantity of circulating blood. For the latter the authors used intravenous injections of colloid solutions of congo red and found that this method caused no accidents (seventy-five instances). Two kinds of decompensation were studied; namely, "plus decompensation," which indicated increased volumes of circulating blood, and "minus decompensation," which indicated small volumes of the circulating blood. The normal figures obtained from the study of individuals with healthy cardiovascular systems showed the circulating plasma to be from 35 to 45 cc. for each kilogram of body weight and the circulating blood to be from 65 to 83 cc. for each kilogram of body weight and the proportion of the entire body weight for plasma was from 3.5 to 4.5 per cent and for circulating blood from 6.5 to 8.3 per cent of the body weight. Pyknotic and hypersthenic individuals had smaller volumes of circulating blood (from 6.5 to 7.4 per cent of body weight) than asthenic individuals (from 8 to 8.3 per cent of body weight). The review of the clinical facts does not show what forms of decompensation are specific for increased or decreased circulating blood volume. Some workers have reported a decreased volume in patients with primary disturbance in the gaseous exchange in the lungs. From the point of view of treatment, patients with plus decompensation were treated with digitalis, the patients ordered to sit with the feet hanging down, and given a diet poor in nitrogen and salt; substances that increase blood circulation volume, such as camphor and caffeine, were also administered. Digitalis in cases of minus decompensation is indicated only according to the condition of the heart. The authors conclude that the whole volume of blood is present in the blood circulation of the body; and a part is present in the various organ depots. All things equal, each individual has a more or less constant volume of blood in his circulation. Patients with compensated conditions of the heart have a normal circulating blood volume; patients with decompensation have either a large circulating or small circulating blood volume: plus or minus decompensation.

**Treatment of Cholecystitis and Angiocholitis with Duodenal Instillations.**—Triger reports that, since 1924, 125 cases of diseases of the biliary tract have been studied in detail and treated by duodenal sound instillations. Treatment consisted of instillation of 40 cc. of from 30 to 33 per cent solutions of magnesium sulphate or, for stronger action, from 40 to 50 cc. of olive oil, every day for three or four days or, for torpid forms, from twelve to sixteen days. Occasionally hypophyseal extracts were also used in treatment. Hospitalization is necessary to insure results. In some instances, in addition to the intubation, the patients also received hot surface applications in the region of the liver, three glasses of mineral water a day, belladonna, papaverine and methenamine. The clinical picture after treatment was characterized (1) by an approach of the physical state of the bile to normal, decrease in leukocytes and a reappearance of the umbilical reflex; (2) by a gradual approach to normal and a reappearance of the umbilical reflex at the end of treatment (the majority were in this group); and (3) by an absence of change in duodenal contents, but improvement, with temperature back to normal, decrease in hepatic pain, decrease in the jaundice, and subjective improvement with disappearance of painful attacks. The treatment should be discontinued if no improvement is noted after two or three instillations. The treatment is indicated in all chronic forms of cholecystitis accompanied by spasms and in parasitic invasions as lambliasis (purely mechanical). Failures in 7 per cent consisted primarily of cases of acute cholangeitis, with large quantities of mucus and leukocytes in C bile, enlarged liver and subfebrile temperature (three of these were lamblia infestations). In some instances, improvement in the cholecystitis was accompanied by disappearance of the migraine and the tachycardia and systolic murmurs.

**Multiple Cystic Degeneration of Kidneys.**—Barkagan states that his detailed case history of multiple cystic degeneration of the kidneys is interesting because, aside from the typical symptoms with characteristic changes in the kidneys, nephritis and uremia, there are clinical manifestations, especially those that relate to the glands of internal secretion. Part of these disturbances were noted during life and part at necropsy. Deficiency on the part of the endocrine glands may be due to a sclerosing process or to defects in development. The author found neither in life nor at necropsy any signs of a chronic infectious process. The cystic process in the instance described spread to the liver and to the pancreas. This disturbance may be present for years without subjective or objective symptoms. The symptoms, when they appear, may be secondary, together with acute azotemia and loss of strength and ability to work; the disease is then in its final stages. An intervention is indicated only when the disease is unilateral with hematuria or a suppurative process in one kidney. Opotherapy should be a symptomatic indication.

Rare Case of Sarcoma of Uterus. H. Okkels and F. Therkelsen.—p. 415.

**Influence of Thyrotoxic Conditions on Arteries.**—Ipsen says that in exophthalmic goiter the foot temperature is higher than in normal cases; if the metabolism is over 130 per cent the foot temperature is above 35.5 C. (95.5 F.). Change in metabolism due to operation causes a fall in the foot temperature, even if the rectal temperature is unaffected. On operation of goiter patients under local anesthesia an acute rise in the foot temperature occurs, explained as a thyrotoxic effect on the arteries, possibly through the sympatheticus. In a case of myxedema, both the metabolism and the foot temperature rose on treatment with thyroidine. In a case of Raynaud's disease the arterial spasms could be checked or reduced parallel to the thyroidine treatment.
